

# Working with Graphics Programming

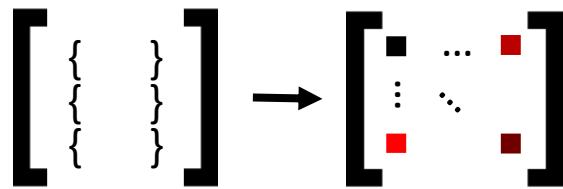

Patrick SARDINHA

# What's a shader?

Small programs that run on the GPU

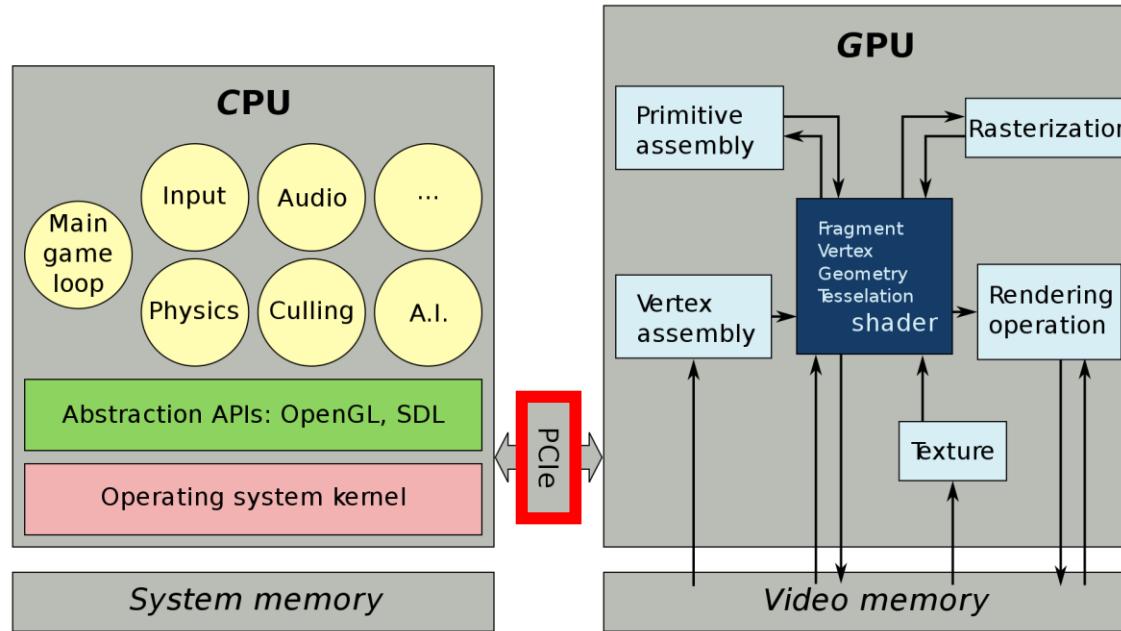

Executed for each specific section of the graphics pipeline

Isolated and not allowed to communicate with each other

It works with geometric primitives, lights, textures, ...

# Shaders in the Graphics Processing Unit

Shaders are executed by the GPU & are good to be executed in parallel

Sending data to the GPU goes through the **PCI**, it is relatively slow  
& CPU/GPU must be synchronized

# Different languages

DirectX High-Level Shader Language

Cg Shader Language

OpenGL Shading Language (GLSL)

# Problem

In GLSL, there are no real data structures to easily get the attributes of a primitive (matrices, vectors, ...)

The construction of shaders is very repetitive which implies a lot of copy and paste

Must reduce the data sent in the PCI to avoid multiple synchronizations between CPU & GPU

# Goal of the project

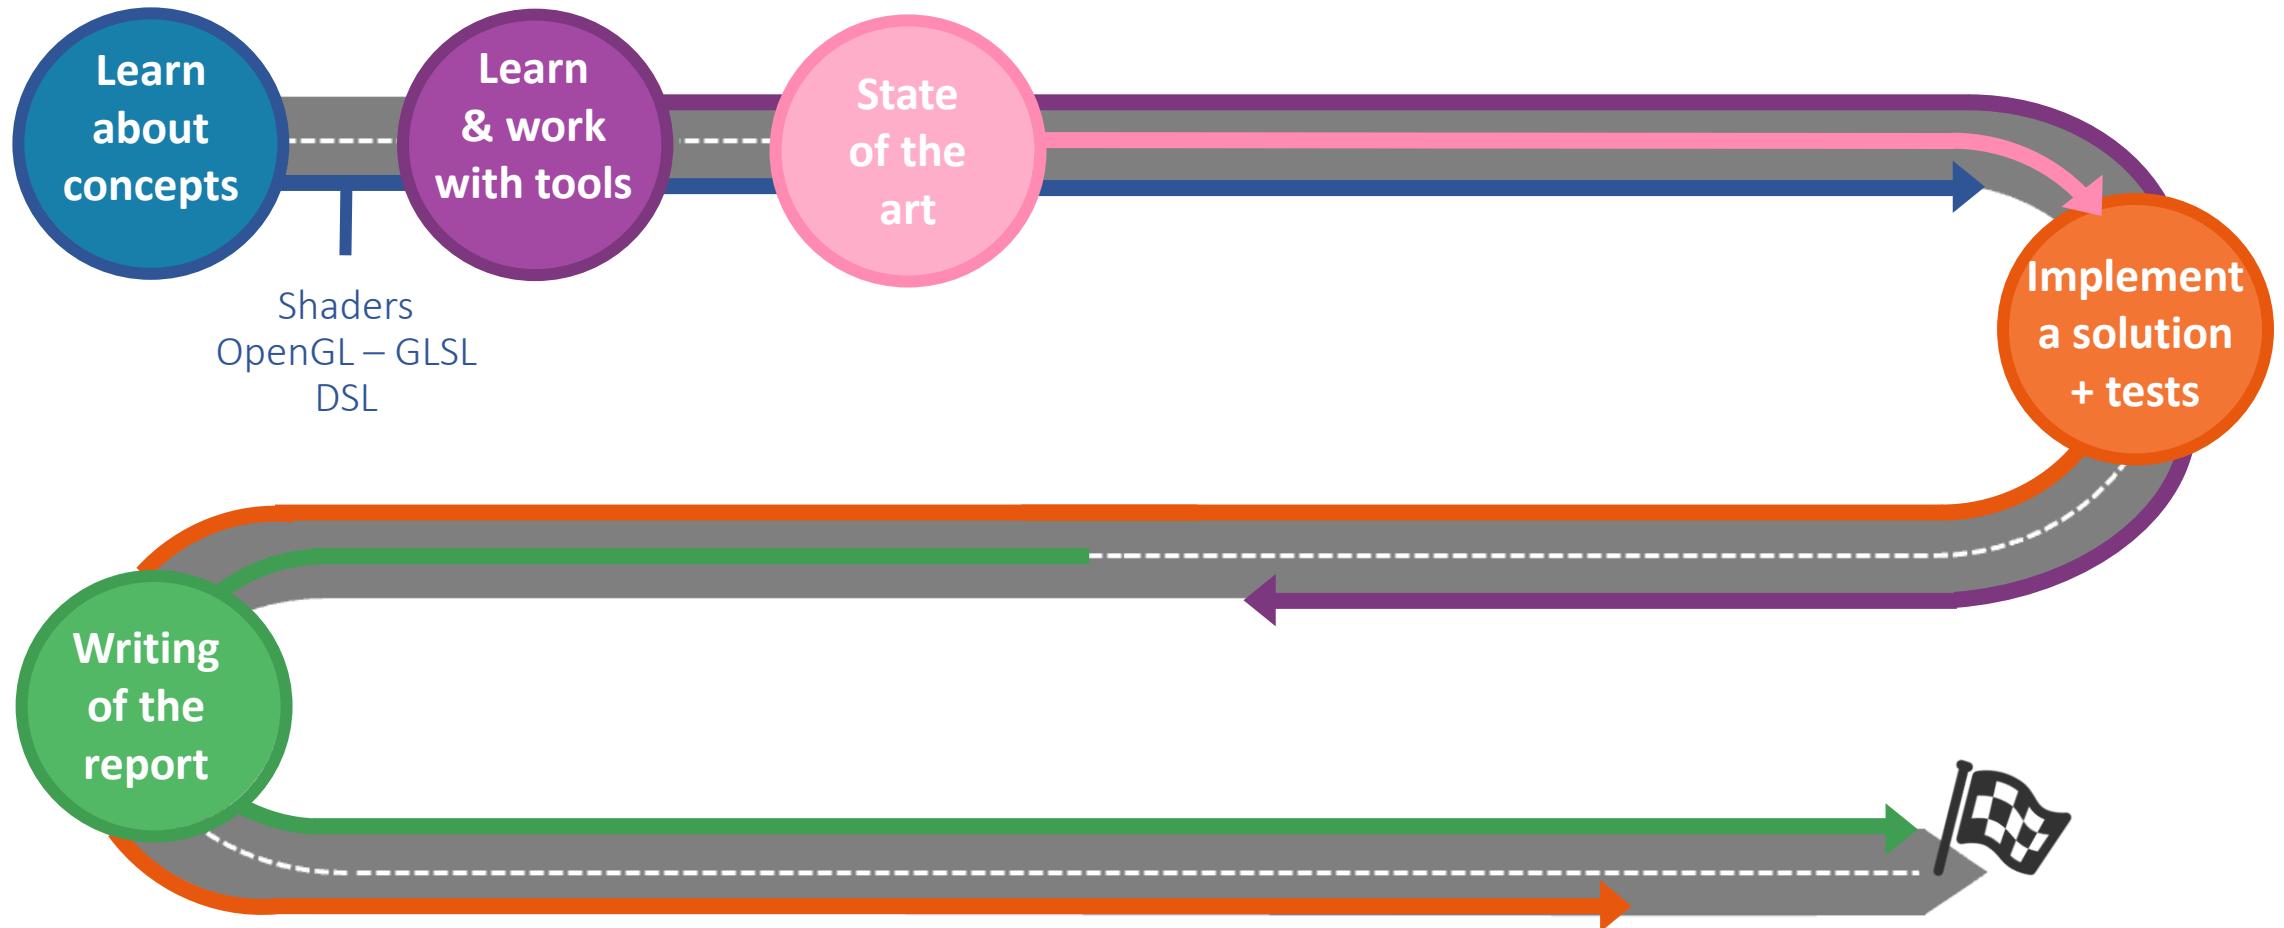

Work with the representation of the data  
& abstract the types

Construct a DSL for shaders

# Road map

# 3D space to 2D screen space

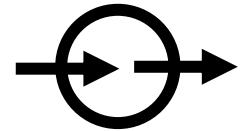

The process of transforming 3D coordinates to 2D pixel is done by the [graphics pipeline](#)

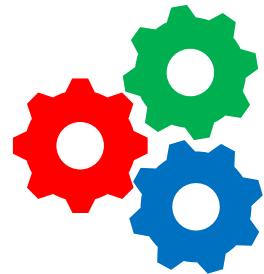

First big part: transforms 3D coordinates into 2D coordinates

Second big part: transforms the 2D coordinates into actual colored pixels

# Graphics pipeline

Input & Output Data

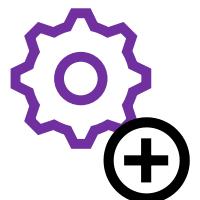

3 different shaders processing units

Vertex Shader

Geometry Shader

Fragment/Pixel Shader

Some others processes

Tessellation, Rasterization, Color blending

# Input Data

[ { - } ]

Take as input a **Vertex (or Vertices) []** which is a data structure that describes geometric primitives with certain attributes like:

Position (2D, 3D coordinates)

Color (RGB, ...)

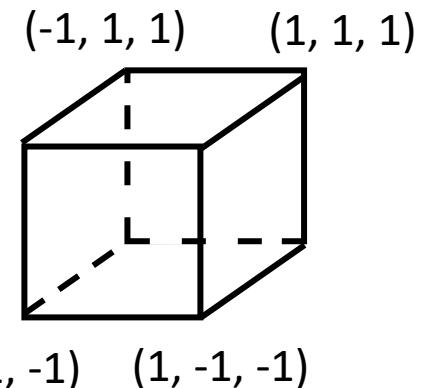

Texture coordinates

# Example

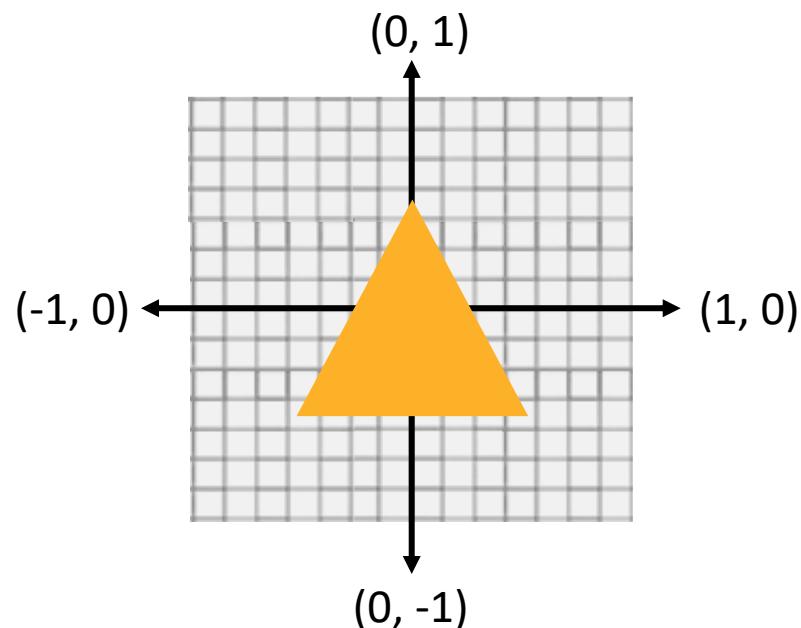

In OpenGL, only the Normalize Device Coordinates (NDC) are visible on the screen

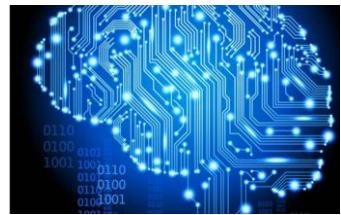

To render a single 2D triangle:

3D position (NDC)  
of each vertex

```
float vertices[] = {  
    [-0.5f, -0.5f, 0.0f,  
     0.5f, -0.5f, 0.0f,  
     0.0f, 0.5f, 0.0f  
};
```

# Linking vertex attributes

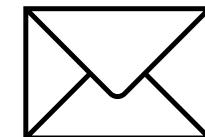

The input data will compose a [Vertex Buffer Object \(VBO\)](#) which can store a large number of vertices in the GPU memory

Then, we specify how the vertex data should be interpreted

Finally, it will be sent to the Vertex Shader

# Example

Triangle with position attributes:

```
float vertices[] = {  
    -0.5f, -0.5f, 0.0f,  
    0.5f, -0.5f, 0.0f,  
    0.0f, 0.5f, 0.0f  
};
```

Copy our vertices array in a buffer

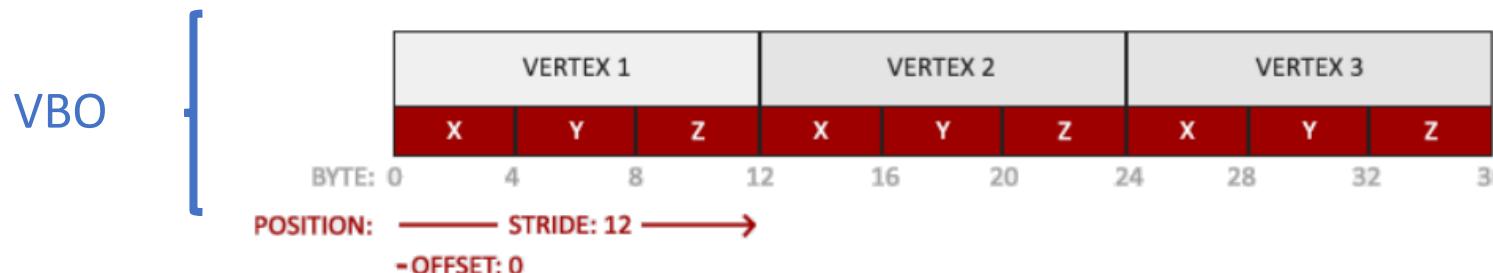

ID of the buffer which must be bind

Specifies the target buffer object

```
glBindBuffer(GL_ARRAY_BUFFER, VBO);  
glBufferData(GL_ARRAY_BUFFER, sizeof(vertices), vertices, GL_STATIC_DRAW);
```

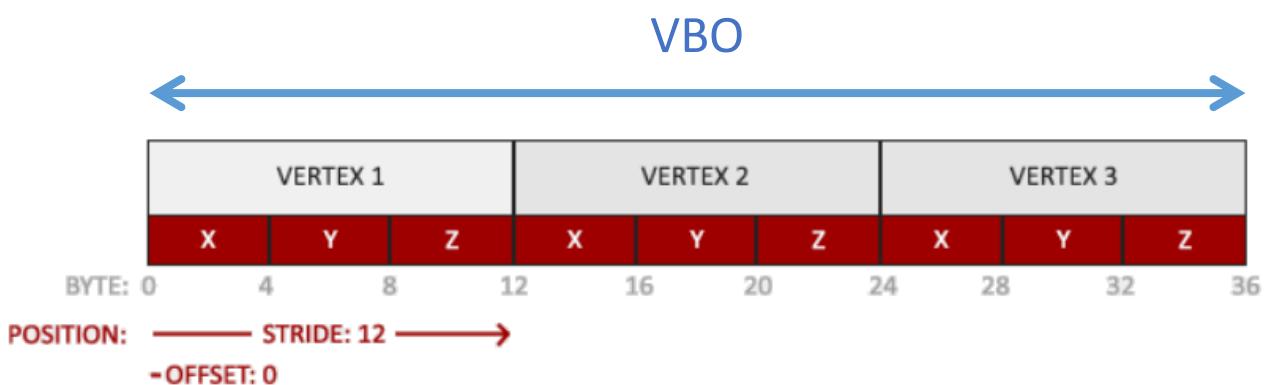

Size of the buffer object

Pointer to data

# Example (Cont.)

Define how the vertex data should be interpreted

```
glVertexAttribPointer(0, 3, GL_FLOAT, GL_FALSE, 3 * sizeof(float), (void*) 0);  
glEnableVertexAttribArray(0);
```

Enable the vertex attribute

Specifies which vertex attribute

The size of the vertex attribute

Type of the data

Normalized data or not

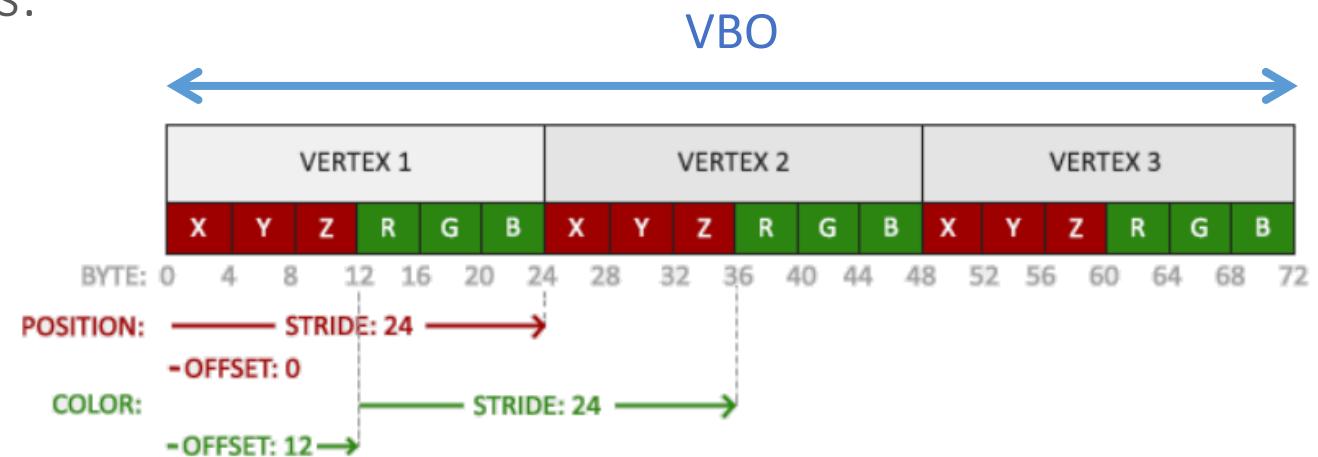

Stride: Space between consecutive vertex attributes

Offset of where the position data begins in the buffer

# Example (Cont.)

Triangle with position & color attributes:

```
float vertices[] = {
    // positions          // colors
    0.5f, -0.5f, 0.0f,  1.0f, 0.0f, 0.0f,
    -0.5f, -0.5f, 0.0f, 0.0f, 1.0f, 0.0f,
    0.0f, 0.5f, 0.0f,  0.0f, 0.0f, 1.0f
};
```

```
// position attribute
glVertexAttribPointer(0, 3, GL_FLOAT, GL_FALSE, 6 * sizeof(float), (void*) 0);
 glEnableVertexAttribArray(0);
// color attribute
glVertexAttribPointer(1, 3, GL_FLOAT, GL_FALSE, 6 * sizeof(float), (void*) (3 * sizeof(float)))
 glEnableVertexAttribArray(1);
```

Stride

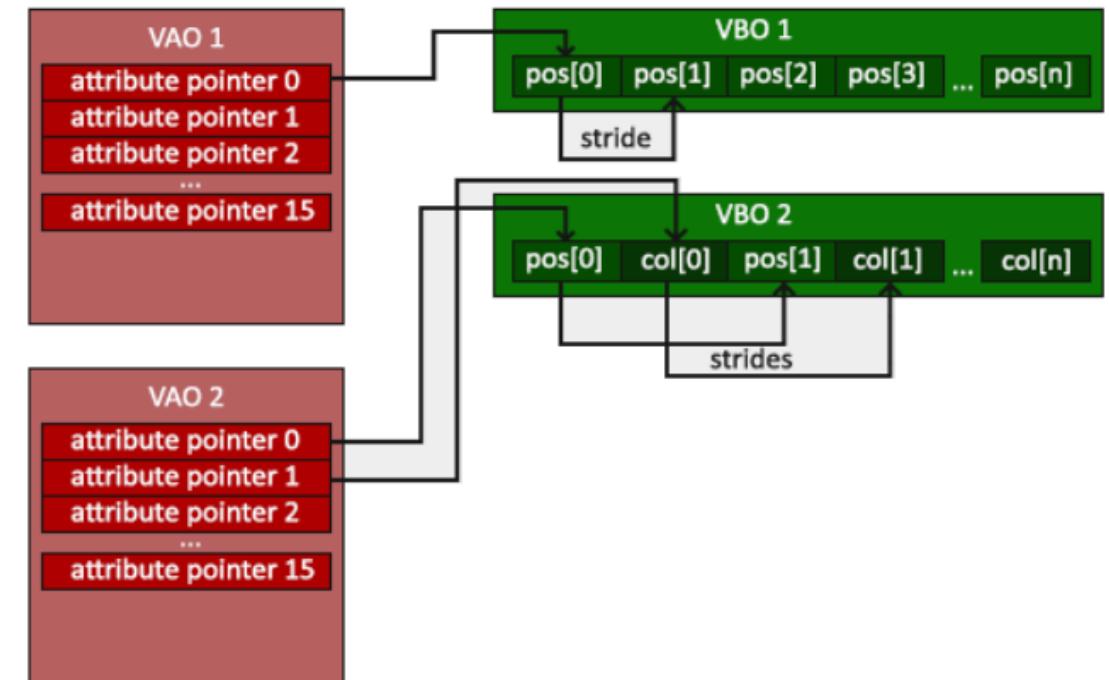

Color offset

# Vertex Array Object (VAO)

Allows to configure vertex attribute pointers more easily

To draw an object, just bind the corresponding VAO

We generate a VAO like a VBO

```
unsigned int VAO;  
glGenVertexArrays(1, &VAO);
```

# Summary

```
// 1. bind Vertex Array Object
glBindVertexArray(VAO);

// 2. copy our vertices array in a buffer for OpenGL to use
glBindBuffer(GL_ARRAY_BUFFER, VBO);
glBufferData(GL_ARRAY_BUFFER, sizeof(vertices), vertices, GL_STATIC_DRAW);

// 3. then set our vertex attributes pointers
glVertexAttribPointer(0, 3, GL_FLOAT, GL_FALSE, 3 * sizeof(float), (void*)0);
 glEnableVertexAttribArray(0);

// (render loop)
// 4. draw the object
glUseProgram(shaderProgram);
glBindVertexArray(VAO);
someOpenGLFunctionThatDrawsOurTriangle();
```

# Render & draw an object

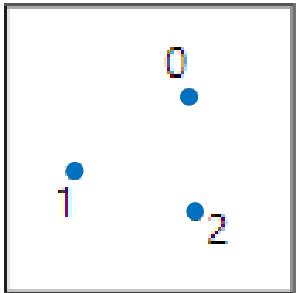

The idea now is to render and draw an object.  
To do that we will have to:

- Set up a Vertex & a Fragment Shader
- Compile these shaders
- Link them to a shader program

# Vertex Shader

Compute the projection of the vertices of primitives from 3D space into a different 3D space (NDC)

Input data: some properties of the vertices  
(position, color or texture coordinates)

Output data: the corresponding properties in the new space

# Sample code

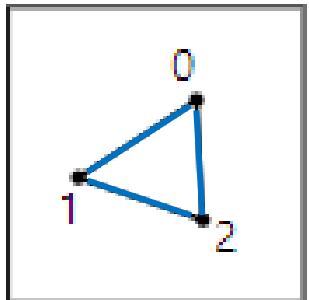

The diagram shows a vertex shader code block with several annotations:

- A red arrow points to the `#version 330 core` directive, labeled "Shader's version (here 3.3)".
- A blue arrow points to the `layout (location = 0)` declaration, labeled "Specifically set the location of the input variable".
- A pink box highlights the `in vec3 aPos;` declaration, labeled "All the input vertex attributes".
- A green bracket underlines the `gl_Position` assignment, labeled "(x, y, z) + w component".
- A red bracket underlines the `aPos.x`, `aPos.y`, and `aPos.z` components.
- A red bracket underlines the `1.0` constant.
- A red arrow points from the bottom left to the `gl_Position` line, labeled "Output of the vertex shader".

```
#version 330 core
layout (location = 0) in vec3 aPos;

void main()
{
    gl_Position = vec4(aPos.x, aPos.y, aPos.z, 1.0);
}
```

# Primitives Assembly

This process takes all the vertex given by the step before and assemble them in order to create a geometric shape

Sample code:

```
glDrawArrays(GL_TRIANGLES, 0, 3);
```

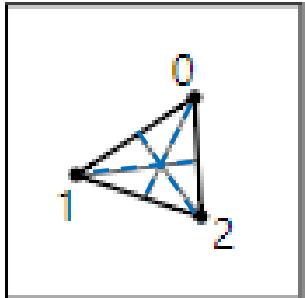

OpenGL function  
that draws a shape

Starting index in the array

Kind of primitive to render

Number of vertices to render

# Tessellation

In 3D, the surfaces are built with triangular tiles

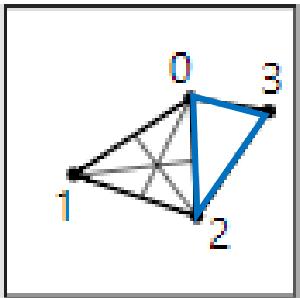

Tessellation allows to double triangles on a given surface  
and therefore increase the level of details

# Geometry Shader

An unnecessary step

Allows to modify the geometry of each polygon and allows to create new polygons by emitting new vertices

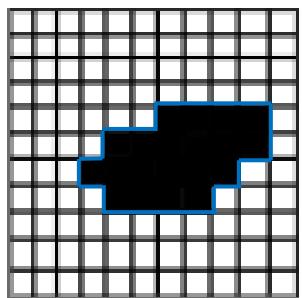

Input data: data of a geometric primitive

Output data: data of one or more geometric primitive

# Rasterization

Method of converting a vector image into a raster image to be displayed on a screen

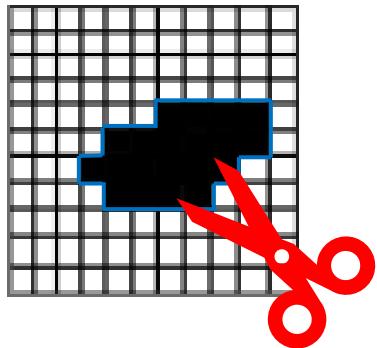

Vector image  
composed of geometric objects

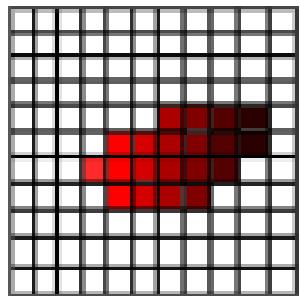

Raster image or Bitmap  
composed of pixels

# Clipping

This step discard all fragments (which is the required data to render a single pixel) that are outside the view, increasing the performance

# Fragment/Pixel Shader

Calculates the final color of a pixel

Input data: pixel data  
(position, texture coordinates, color)

Output data: the pixel color

# Sample code

Shader's version (here 3.3)

Output variable which is the final color output

```
#version 330 core
out vec4 FragColor;

void main()
{
    FragColor = vec4(1.0f, 0.5f, 0.2f, 1.0f);
```

RGB + alpha component

# Compile a Shader

First, we store the code in a string constant

```
const char *vertexShaderSource = "#version 330 core\n"
    "layout (location = 0) in vec3 aPos;\n"
    "void main()\n"
    "{\n        gl_Position = vec4(aPos.x, aPos.y, aPos.z, 1.0);\n    }\0";
```

Then, we store and create the shader

```
unsigned int vertexShader;
vertexShader = glCreateShader(GL_VERTEX_SHADER);
```

Type of shader we want to create

Finally, we link the source code to the object and compile it

```
glShaderSource(vertexShader, 1, &vertexShaderSource, NULL);
glCompileShader(vertexShader);
```

# Shader program

First, we create a program object

```
unsigned int shaderProgram;  
shaderProgram = glCreateProgram();
```

We attach the previously compiled shaders to the program object and link them

```
glAttachShader(shaderProgram, vertexShader);  
glAttachShader(shaderProgram, fragmentShader);  
glLinkProgram(shaderProgram);
```

We can now activate this program to render and draw an object

```
glUseProgram(shaderProgram);
```

Final step is to delete our shader objects

```
glDeleteShader(vertexShader);  
glDeleteShader(fragmentShader);
```

# Uniforms variables

Useful to pass data from the application on the CPU  
to the shaders on the GPU

These are global variables

Sample code:

Usage of uniform keyword

```
#version 330 core
out vec4 FragColor;

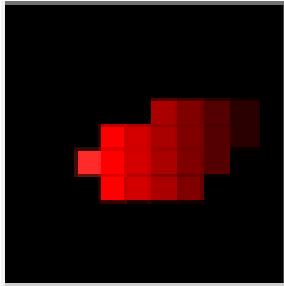

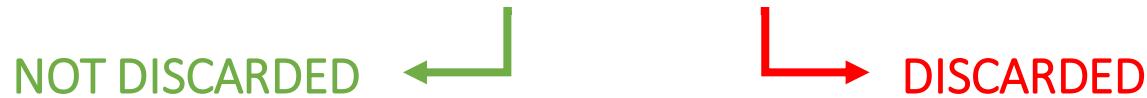

uniform vec4 ourColor;

void main()
{
    FragColor = ourColor;
}
```

# Alpha test

Checks the corresponding depth value of a fragment to see if the resulting fragment is **in front** or **behind** another one

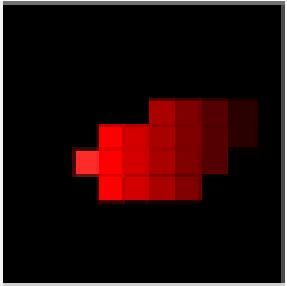

Done with the depth testing using a **Z-buffer** (in which the depth value of the fragments is stored)

```
glEnable(GL_DEPTH_TEST);
```

Then, checks for alpha values (opacity of an object)  
& blends the objects

# Color Blending

The technique of gently blending two or more colors to create a gradual transition

# Example of a blending function

First, we have to enable the OpenGL functionality

```
glEnable(GL_BLEND);
```

Then, blending can follow this equation:

$$\bar{C}_{result} = \bar{C}_{source} * F_{source} + \bar{C}_{destination} * F_{destination}$$

Final color of the fragment

Impact of the alpha value

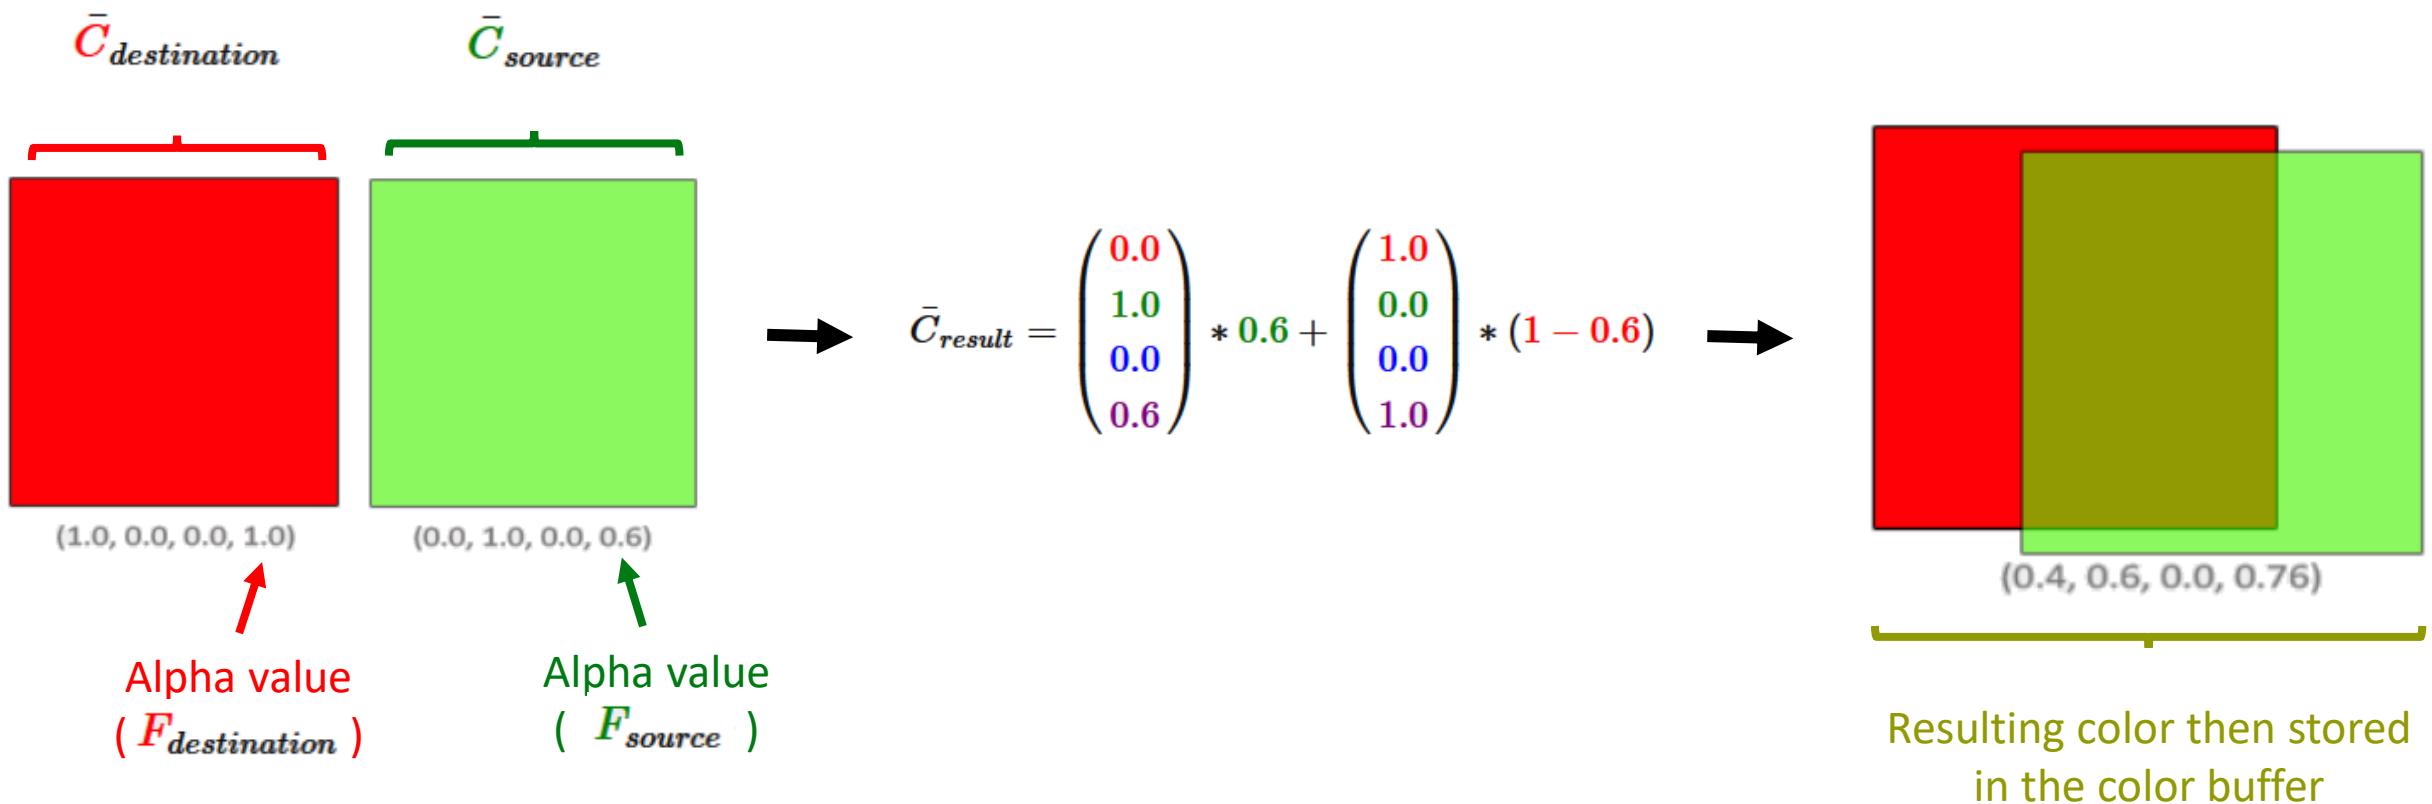

Color output of the fragment shader

Impact of the alpha value

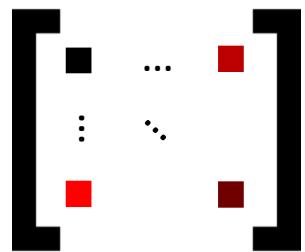

Color currently stored in the color buffer

## Example (Cont.)

$$\bar{C}_{result} = \bar{C}_{source} * F_{source} + \bar{C}_{destination} * F_{destination}$$

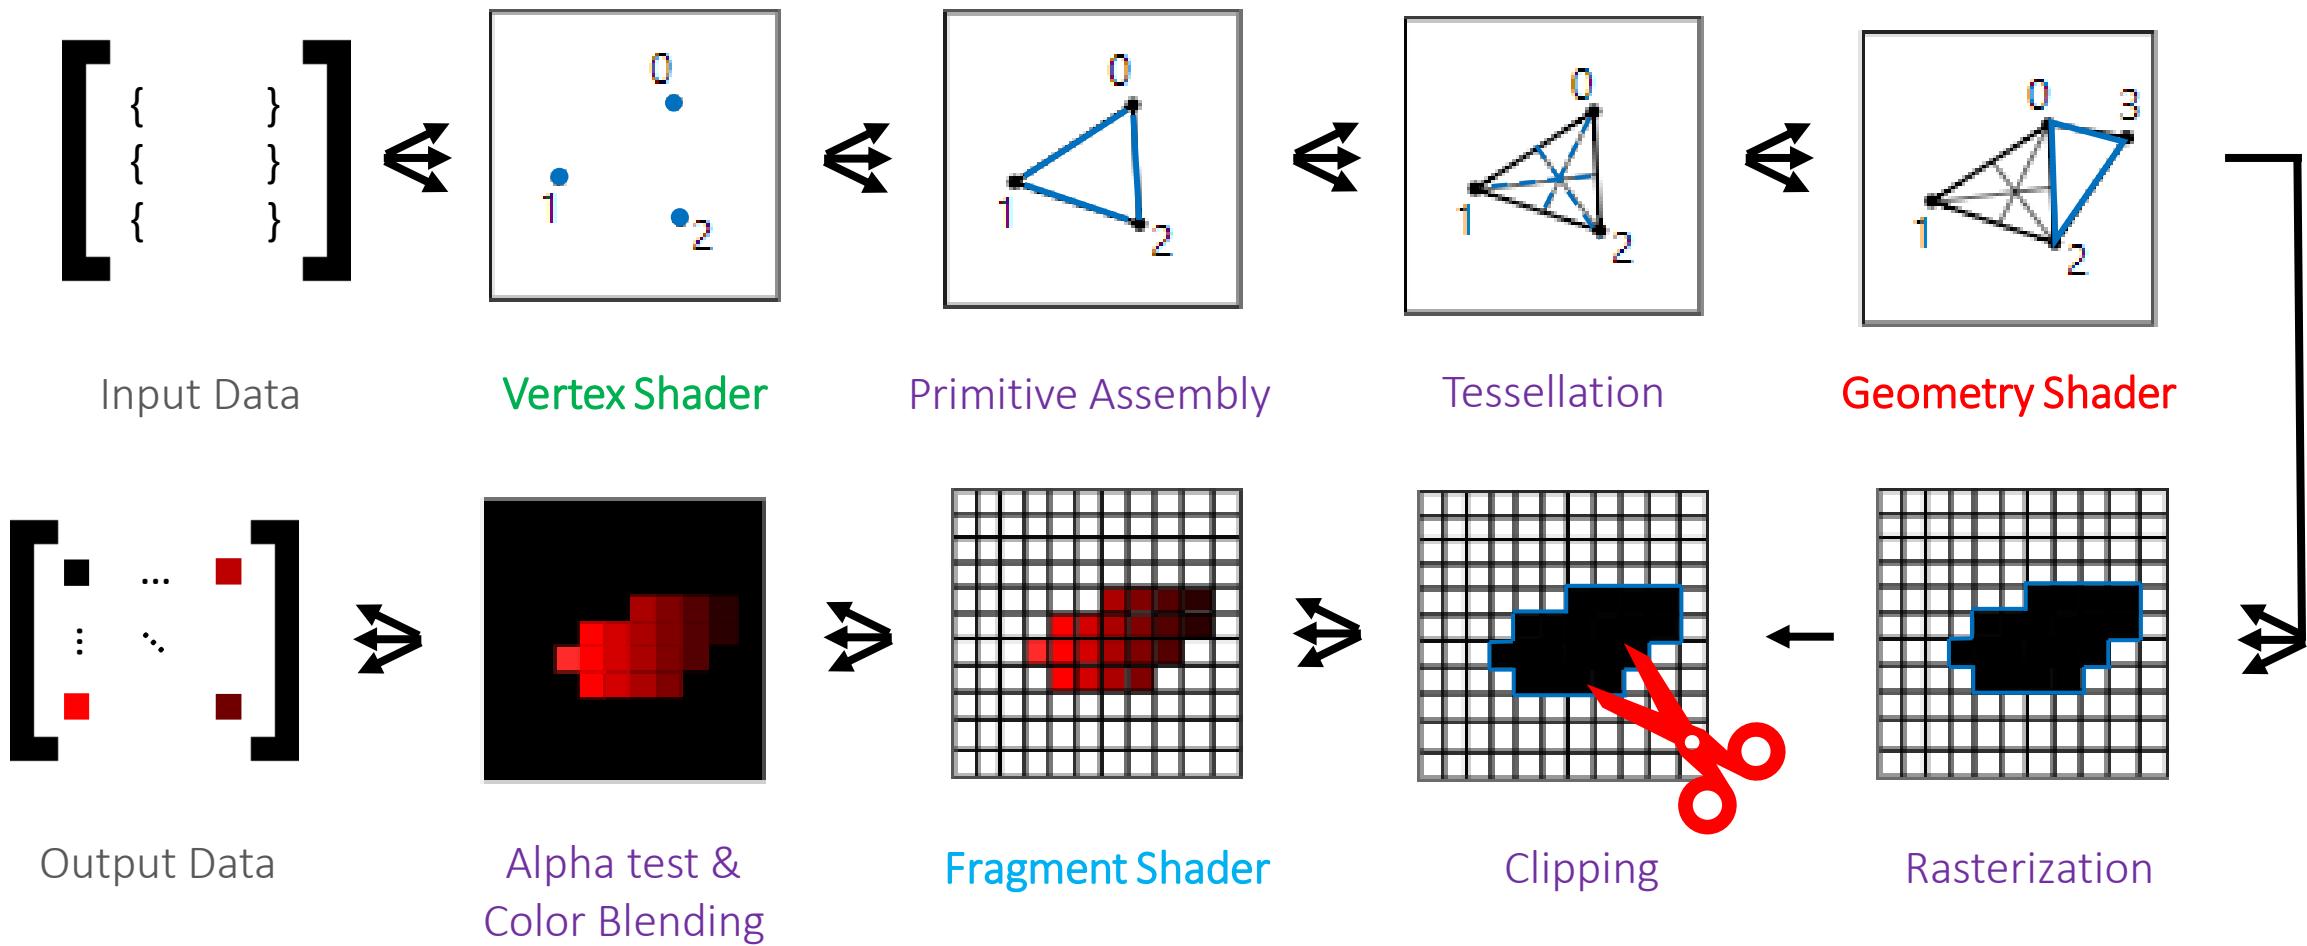

# Output Data

Return a **Framebuffer**

The information in this buffer are the values of the color components (**RGB**) for each pixel

# Overall view

# Textures

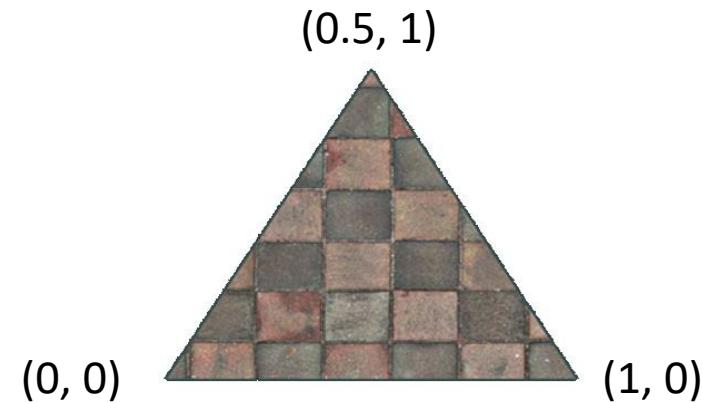

Allows to give the illusion the object is detailed without having to specify vertices

Associate each vertex to a texture coordinate

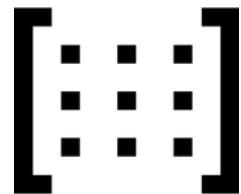

A fragment interpolation is then done for the other fragments

Sample code:

```
float texCoords[] = {  
    0.0f, 0.0f, // lower-left corner  
    1.0f, 0.0f, // lower-right corner  
    0.5f, 1.0f // top-center corner  
};
```

# Transformations

Make an object dynamic using matrix objects  
& by combining the matrices

Some library can be used like the GLM (OpenGL Mathematics) library

# Useful matrices

## Scaling Matrix

$$\begin{bmatrix} S_1 & 0 & 0 & 0 \\ 0 & S_2 & 0 & 0 \\ 0 & 0 & S_3 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} S_1 \cdot x \\ S_2 \cdot y \\ S_3 \cdot z \\ 1 \end{pmatrix}$$

## Translation Matrix

$$\begin{bmatrix} 1 & 0 & 0 & T_x \\ 0 & 1 & 0 & T_y \\ 0 & 0 & 1 & T_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} x + T_x \\ y + T_y \\ z + T_z \\ 1 \end{pmatrix}$$

## Rotation Matrix

### Around X-axis

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta & 0 \\ 0 & \sin \theta & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} x \\ \cos \theta \cdot y - \sin \theta \cdot z \\ \sin \theta \cdot y + \cos \theta \cdot z \\ 1 \end{pmatrix}$$

### Around Y-axis

$$\begin{bmatrix} \cos \theta & 0 & \sin \theta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \theta & 0 & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} \cos \theta \cdot x + \sin \theta \cdot z \\ y \\ -\sin \theta \cdot x + \cos \theta \cdot z \\ 1 \end{pmatrix}$$

### Around Z-axis

$$\begin{bmatrix} \cos \theta & -\sin \theta & 0 & 0 \\ \sin \theta & \cos \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} x \\ y \\ z \\ 1 \end{pmatrix} = \begin{pmatrix} \cos \theta \cdot x - \sin \theta \cdot y \\ \sin \theta \cdot x + \cos \theta \cdot y \\ z \\ 1 \end{pmatrix}$$

# Sample code

Translating a vector of (1,0,0) by (1,1,0)

```
trans = glm::translate(trans, glm::vec3(1.0f, 1.0f, 0.0f));  
vec = trans * vec;
```

Multiply vec by the translation matrix

The matrix to transform (identity Matrix4)

A translate function

The translation vector to apply to the matrix

# Coordinates system

Transforming coordinates to NDC is done by a process regrouping several intermediate coordinate systems

Local Space

World Space

View Space

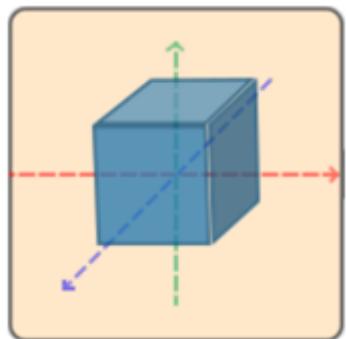

Clip Space

Screen Space

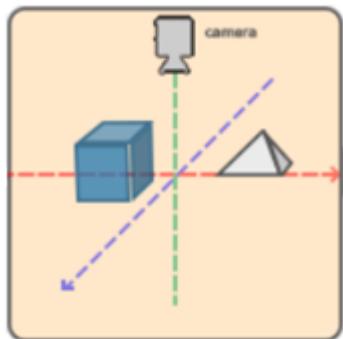

# Local Space

Coordinates of the object relative to its local origin

In general, all new objects have  $(0, 0, 0)$  as initial position

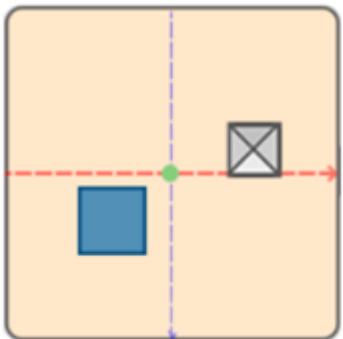

# World Space

Coordinates of all the objects are relative to some global origin of the world

We use a model matrix which translates, scales and/or rotates the object to place it in the world

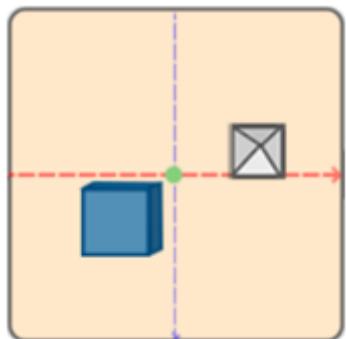

# View Space

Each coordinate is seen from the camera's point of view

This is done by a combination of translations & rotations of the scene which is stored in a [view matrix](#)

# Clip Space

Each coordinates is seen from the camera's point of view

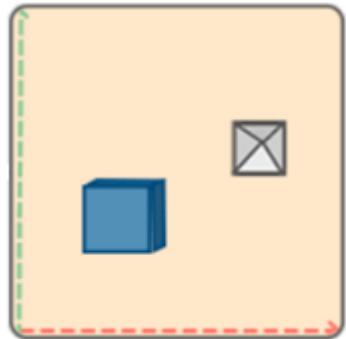

For this step, we use a projection matrix which transform the coordinates into NDC

Example:

Specified range [-1000, 1000] for each dimension

$(1250, 500, 750)$	$\rightarrow$	Not visible
$(900, 500, 750)$	$\rightarrow$	Visible

# Screen Space

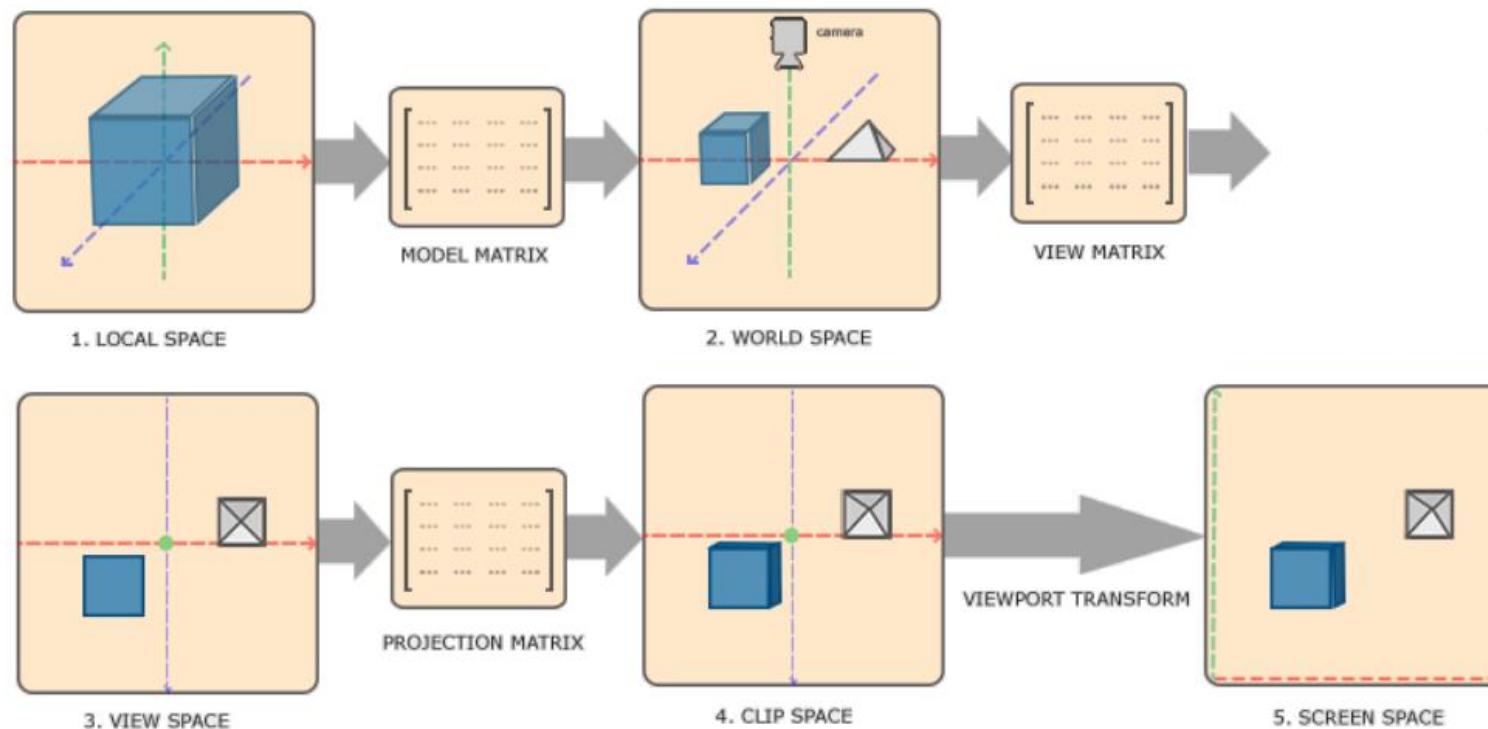

Transforms the NDC coordinates to the window coordinates with the `glViewport()` function

Resulting coordinates are then sent to the rasterizer

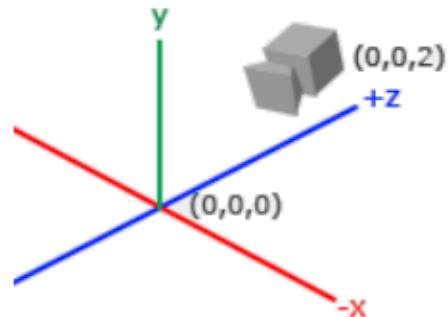

# Overall view

A vertex coordinate is transformed to clip coordinates as follow:  $V_{clip} = \underline{M_{projection} \cdot M_{view} \cdot M_{model} \cdot V_{local}}$

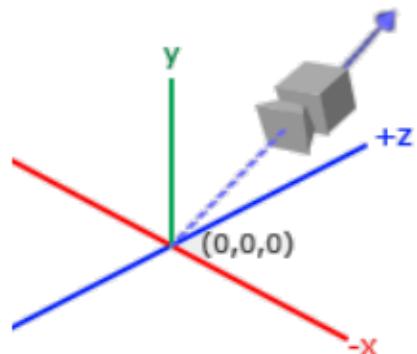

# Camera

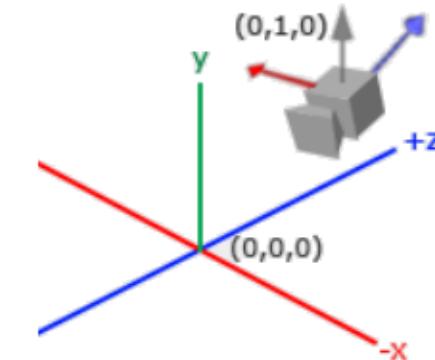

To define a camera we need 4 pieces of information

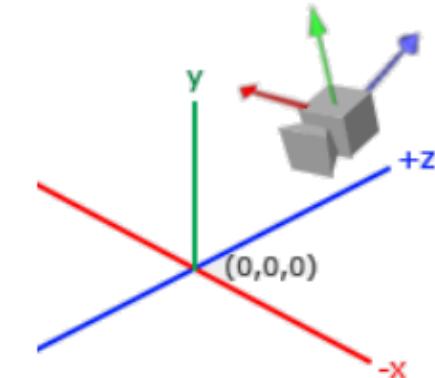

1. Its position in the world space

2. Its direction

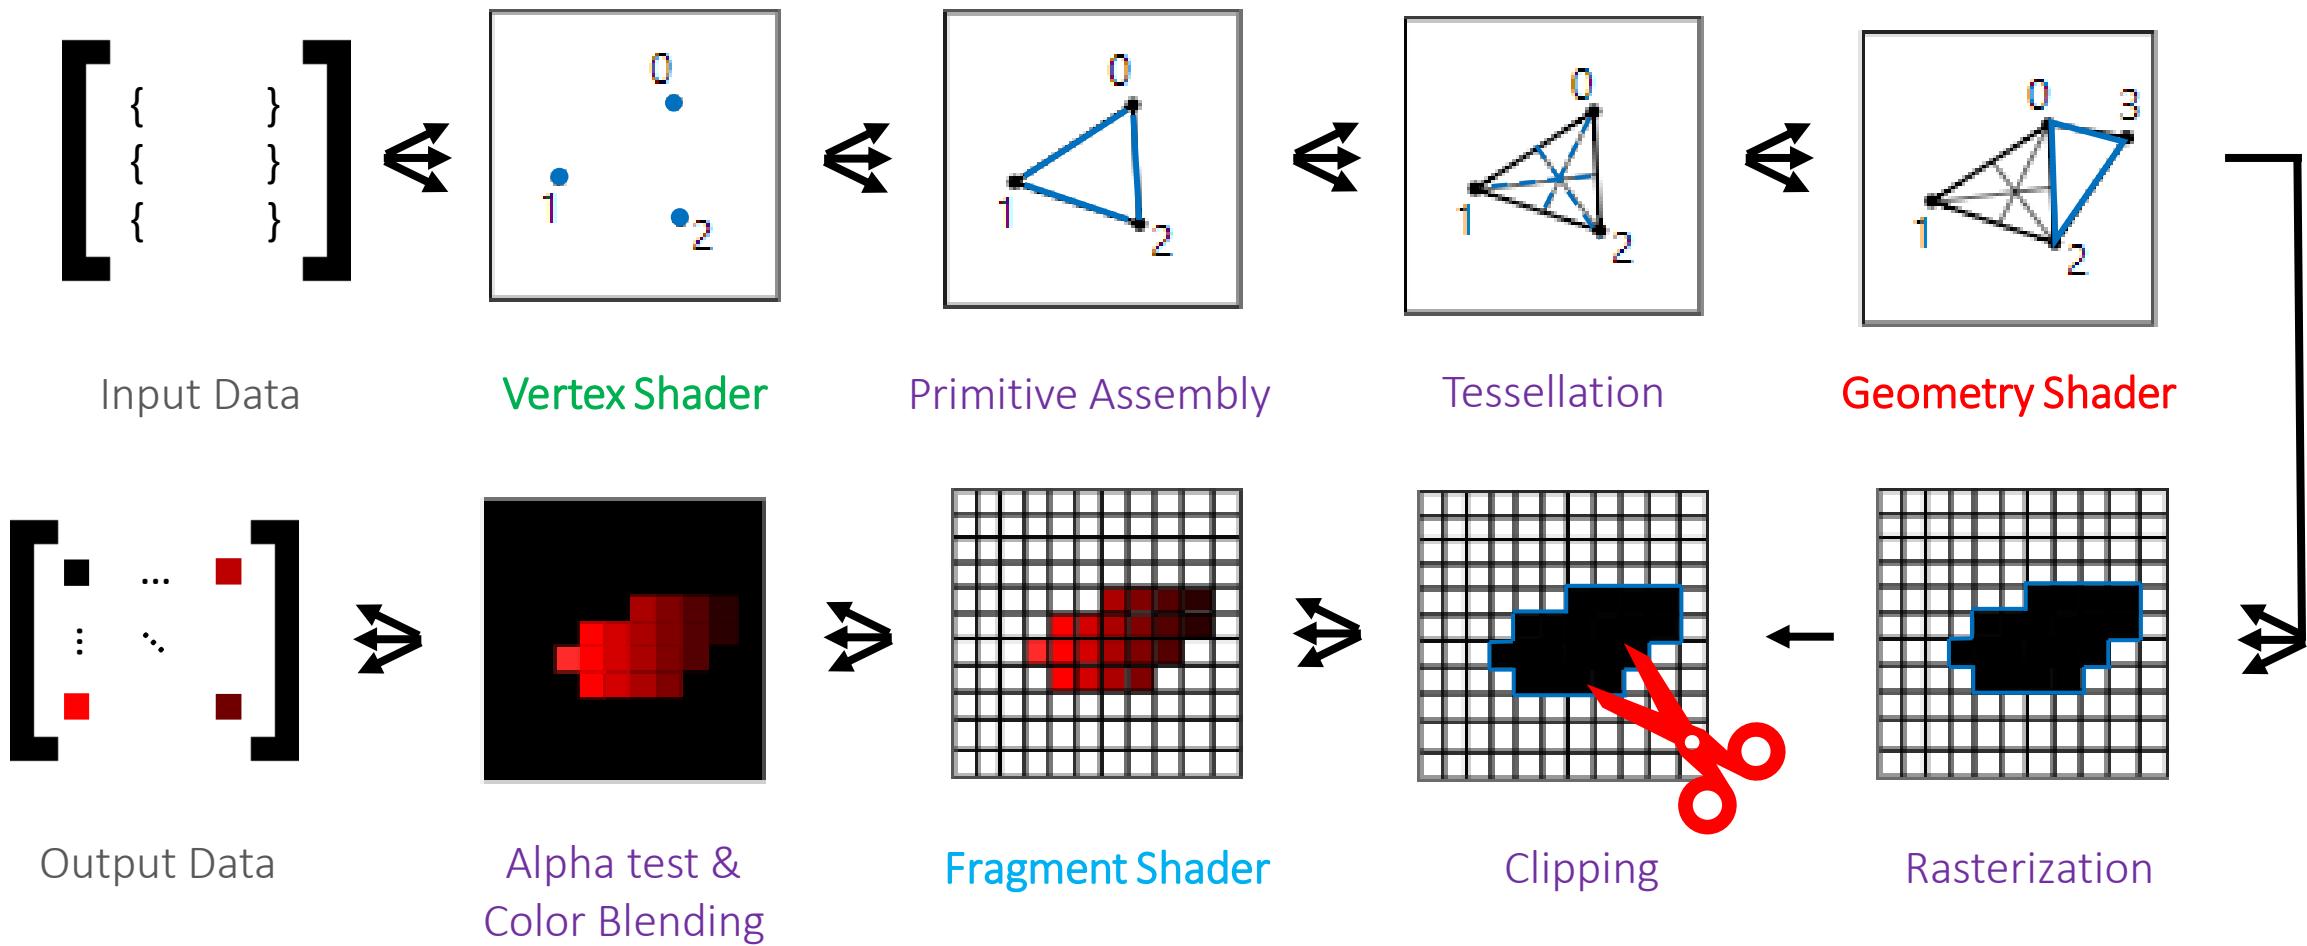

3. A vector pointing to the right

4. A vector pointing upwards

# Recall : Graphics pipeline

# Pipeline abstraction

We can see the pipeline as a function composition  
which can give us:

$$output\_data = (cb \circ at \circ \text{fs} \circ c \circ r \circ t \circ pa \circ \text{vs}) (input\_data)$$

Fragment Shader function

Vertex Shader function

# Context

We can define the notion of context that gives us the valid constants for a run (see after [Uniforms](#))

The formula below is applied for every run

$$output\_data = (cb \circ at \circ fs \circ c \circ r \circ t \circ pa \circ vs) (input\_data)$$

# Recall: Input data

A VBO is built containing the attributes of all vertices  
which give us a huge vector of data

To work with that, we have to use offsets, strides, etc.

# Idea of the abstraction

No longer working with containers of type

Ex: vec3, vec4, ivec4, mat4, ...

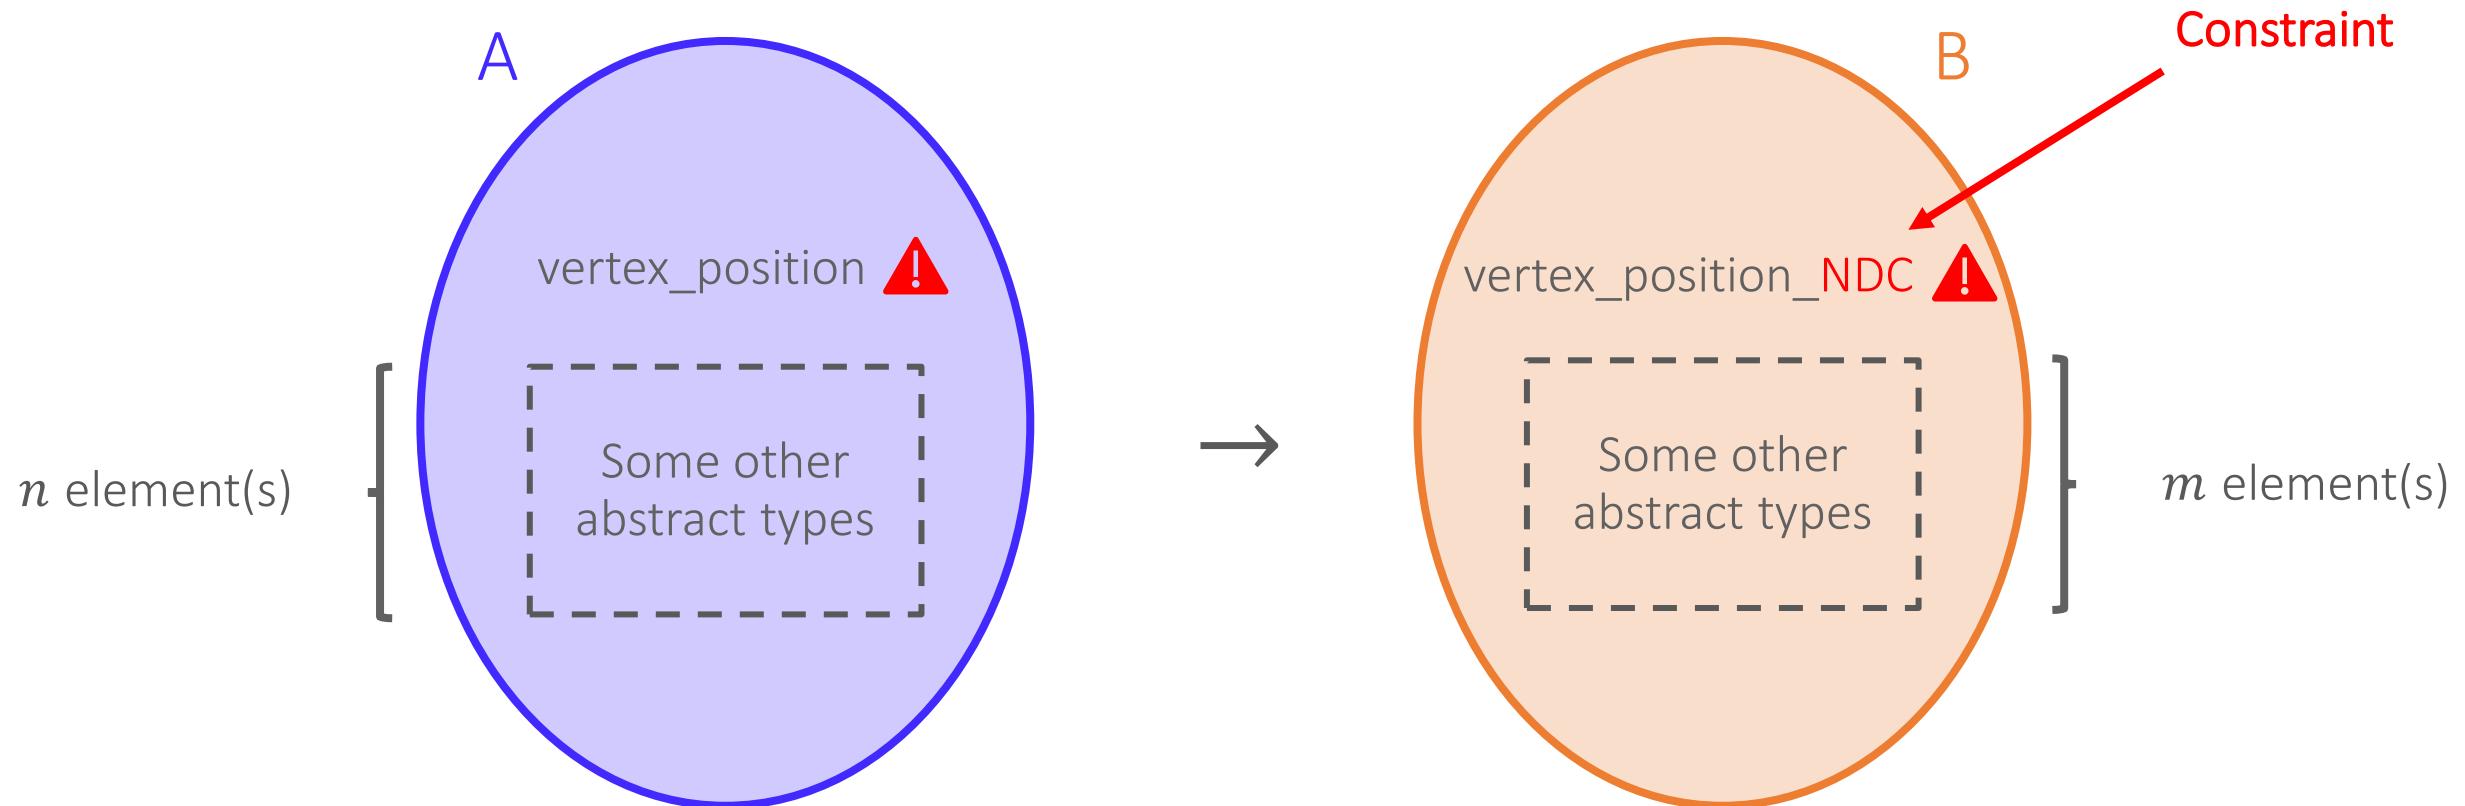

But with abstract type objects

Ex: color, position, textures, ...

# Vertex Shader function

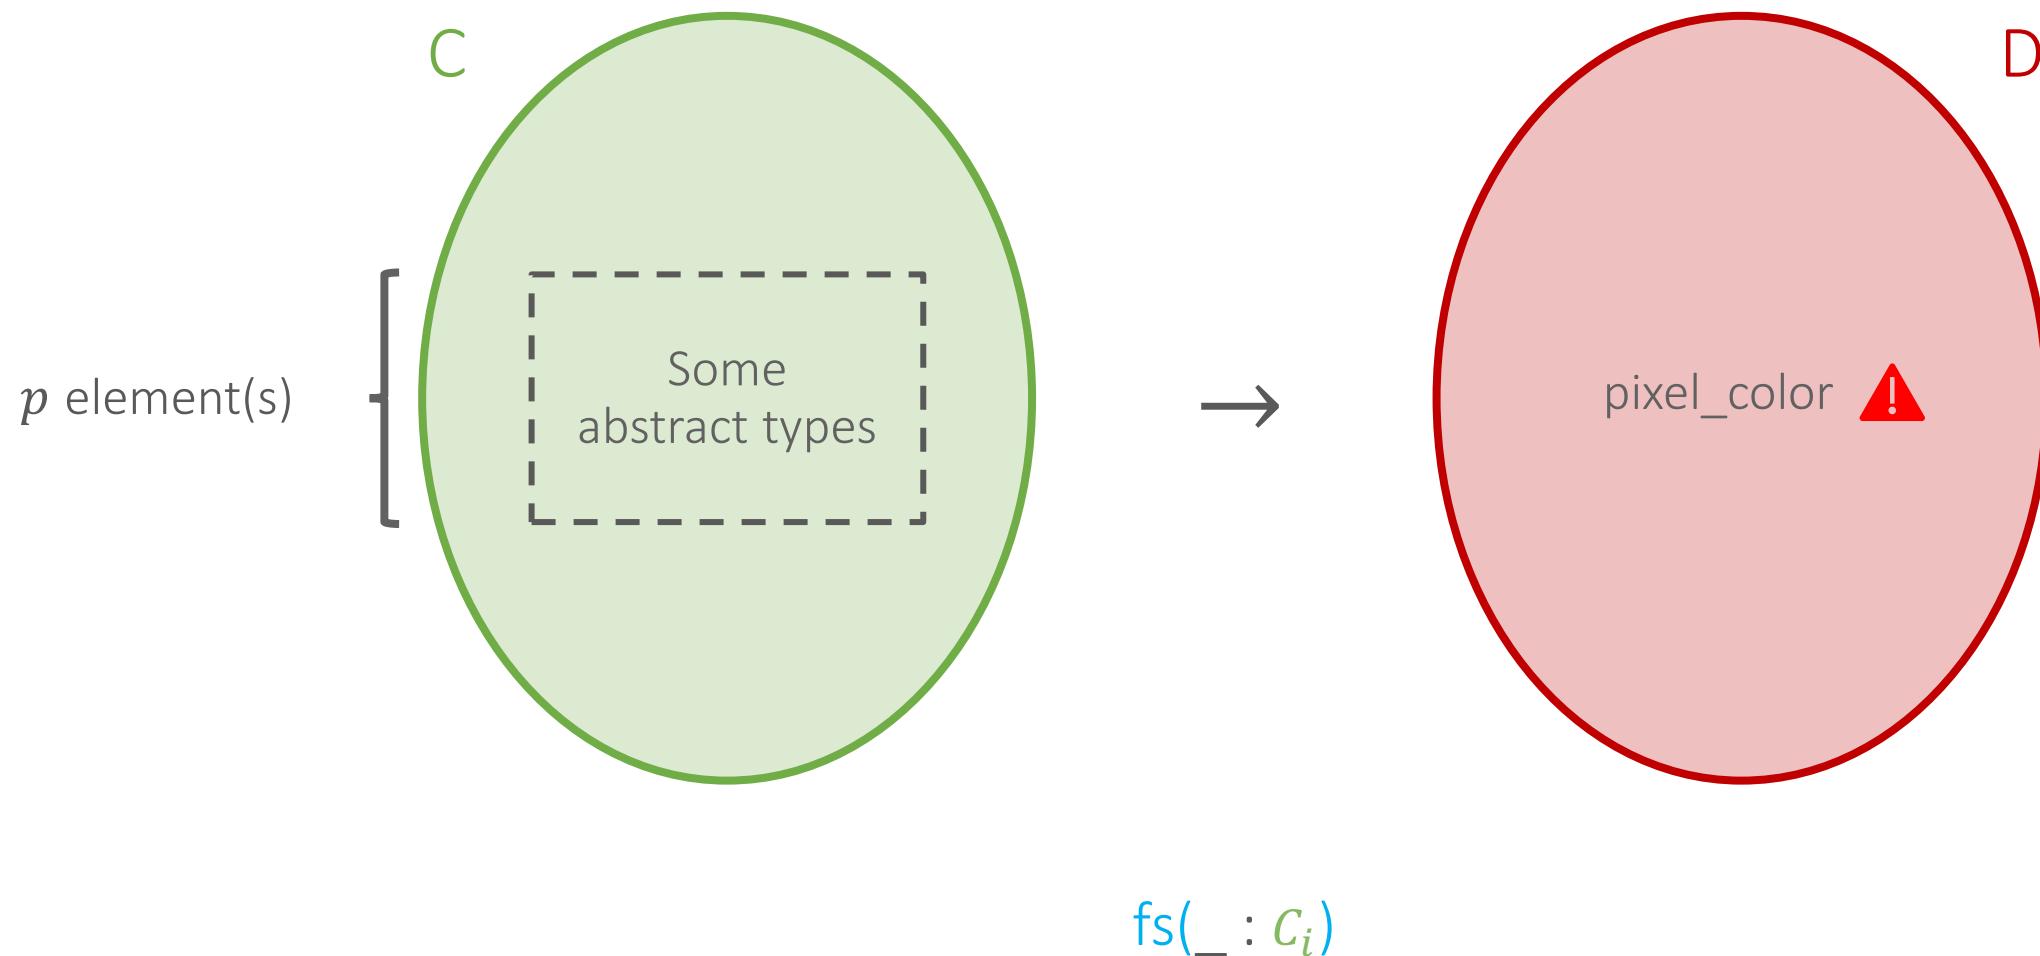

$\text{vs} : A \rightarrow B$

$\text{vs}(\_ : \text{vertex\_position}, \cup \_ : (A_i \setminus \text{vertex\_position}))$

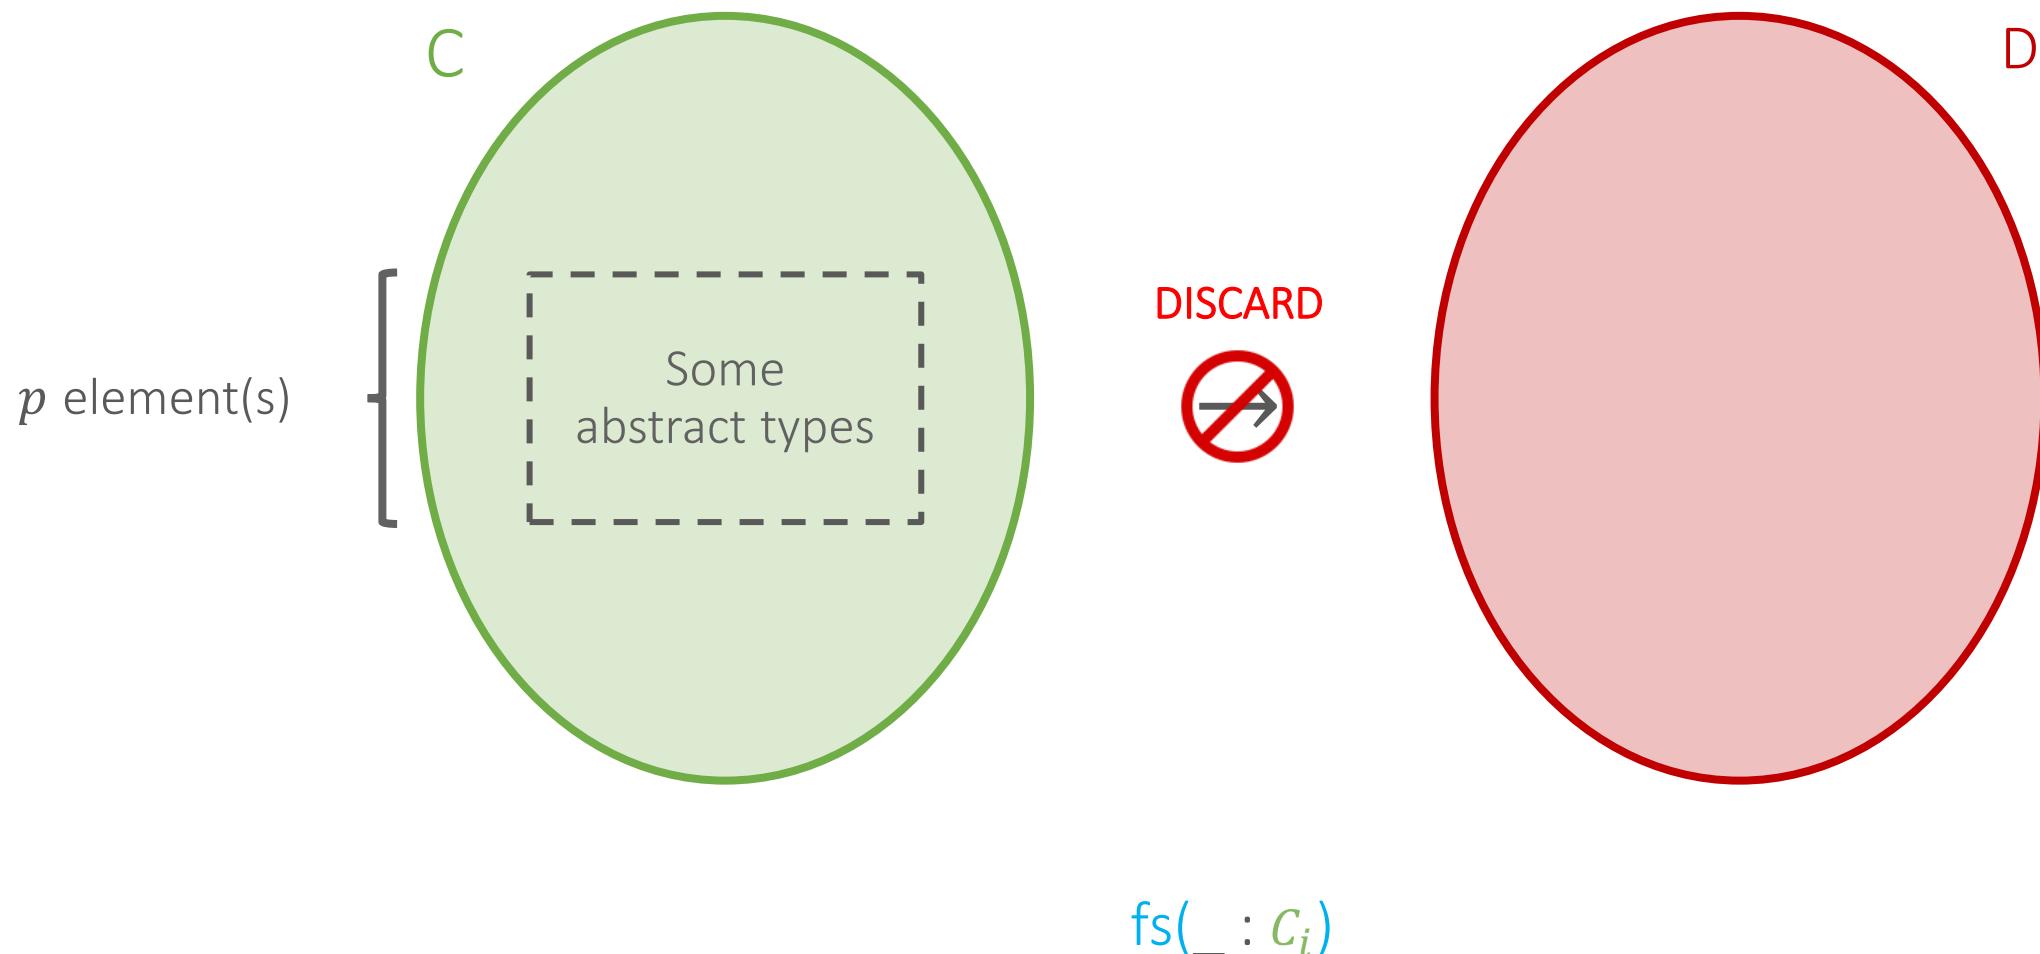

# Fragment Shader function

$\text{fs} : \mathcal{C} \rightarrow \mathcal{D}$

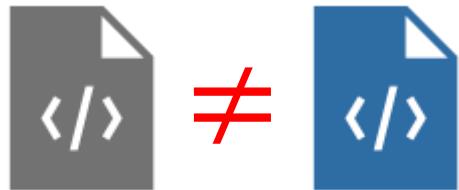

# Fragment Shader function Alternative

$fs : C \rightarrow D$

# Several signatures

Depending on why a shader is created,  
the signature will be different

Examples:

`vs(_ : position)`

`fs()`

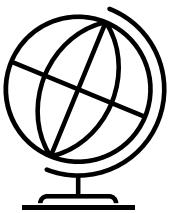

`vs(_ : position, _ : color)`

`fs(_ : fragment, _ : light:)`

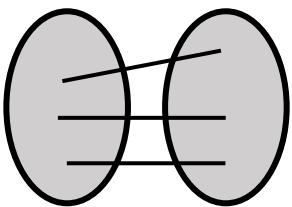

`vs(_ : position, _ : color, _ : texture:)`

`fs(_ : fragment, _ : light, _ : texture:)`

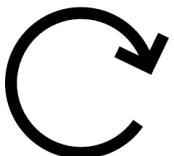

# Uniforms

We saw that uniform variables are global variables

They are part of the domain and  
the codomain of the `vs()` & `fs()` function

These variables are set for a run and define the context

# Type checking between vs() & fs()

Check that names and types variables shared between the vertex & the fragment shader are identical

Example:

```
#version 330 core
layout (location = 0) in vec3 aPos;

out vec4 vertexColor;

void main()
{
    gl_Position = vec4(aPos, 1.0);
    vertexColor = vec4(0.5, 0.0, 0.0, 1.0);
}
```

Vertex shader

```
#version 330 core
out vec4 FragColor;

in vec4 vertexColor;

void main()
{
    FragColor = vertexColor;
}
```

Fragment shader

# Recall : Different languages

DirectX High-Level Shader Language  
(Unreal Engine)

Cg Shader Language  
(Unity)

OpenGL Shading Language

# Similar structures

A sample Cg vertex shader:

Types definition

Calculate output  
coordinates & colors

Output

```
// input vertex
struct VertIn {
    float4 pos    : POSITION;
    float4 color  : COLOR0;
};

// output vertex
struct VertOut {
    float4 pos    : POSITION;
    float4 color  : COLOR0;
};

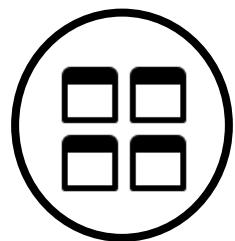

// vertex shader main entry
VertOut main(VertIn IN, uniform float4x4 modelViewProj) {
    VertOut OUT;
    OUT.pos     = mul(modelViewProj, IN.pos);
    OUT.color   = IN.color;
    return OUT;
}
```

Uniform keyword

# Same abstraction

The different shader languages are very similar

We could therefore use the same abstraction for any language

# Domain-Specific Language (DSL)

A DSL is a programming language whose specifications allow to overcome some constraints in a specific domain

The specific domain will be for us the shaders  
and especially vertex & fragment shaders

# Advantages & disadvantages

DSL will allow us to gain in productivity

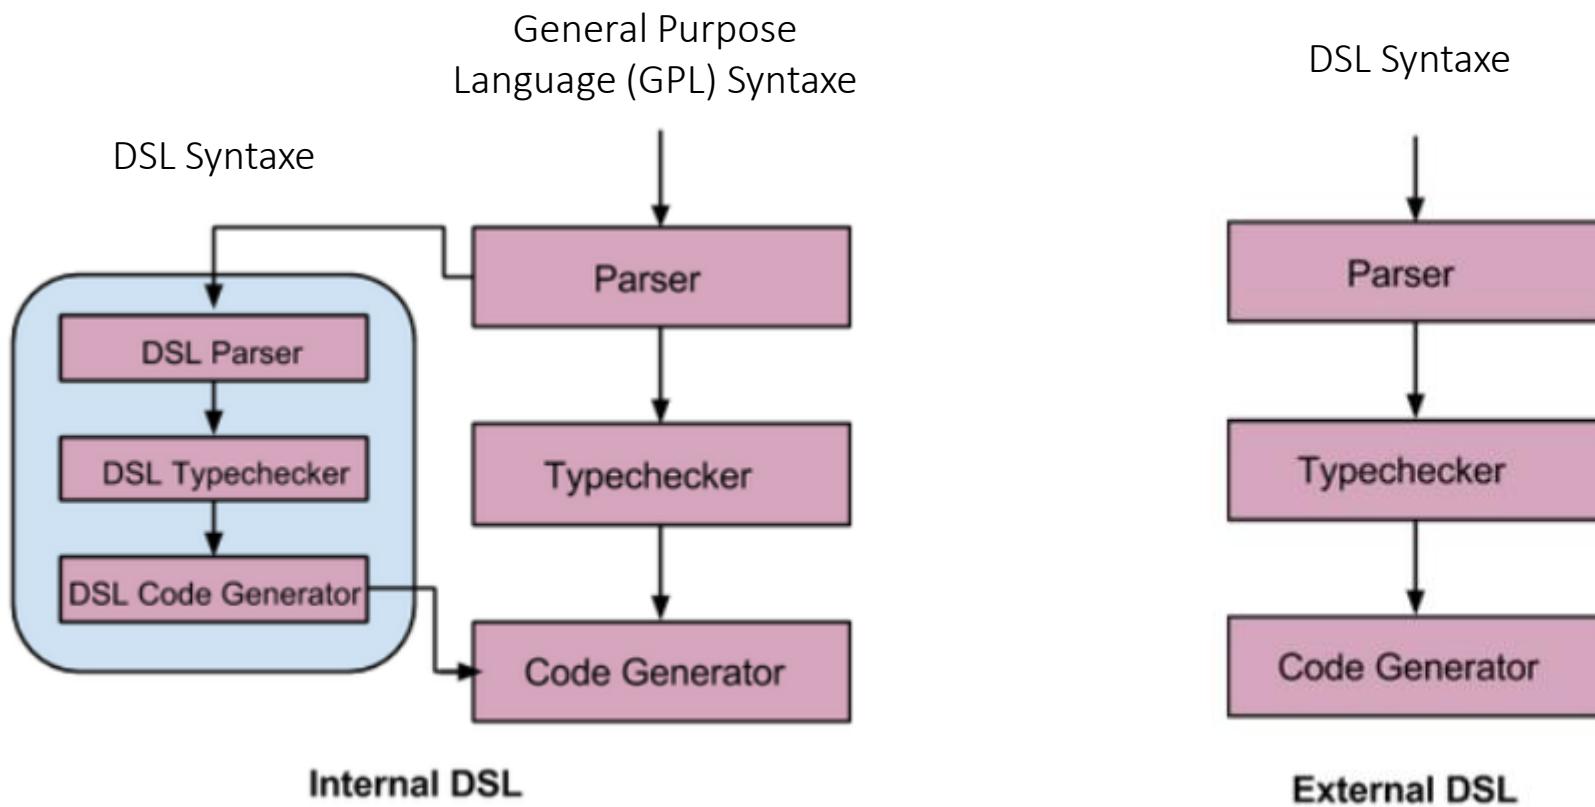

DSL can be reused for other purposes

DSL maintenance is complicated

The cost of a DSL is expensive

# Different types of DSL

# Our way

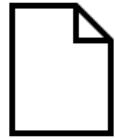

First, we will go on an Internal DSL based  
on the Swift language

Later, we can potentially encounter  
a lot of constraints relating to Swift

If so, we will go on an External DSL at this time

# Main idea

We write in our program a vertex & a fragment shader with our DSL

We send them to an encoder which will translate the abstract types into containers of types

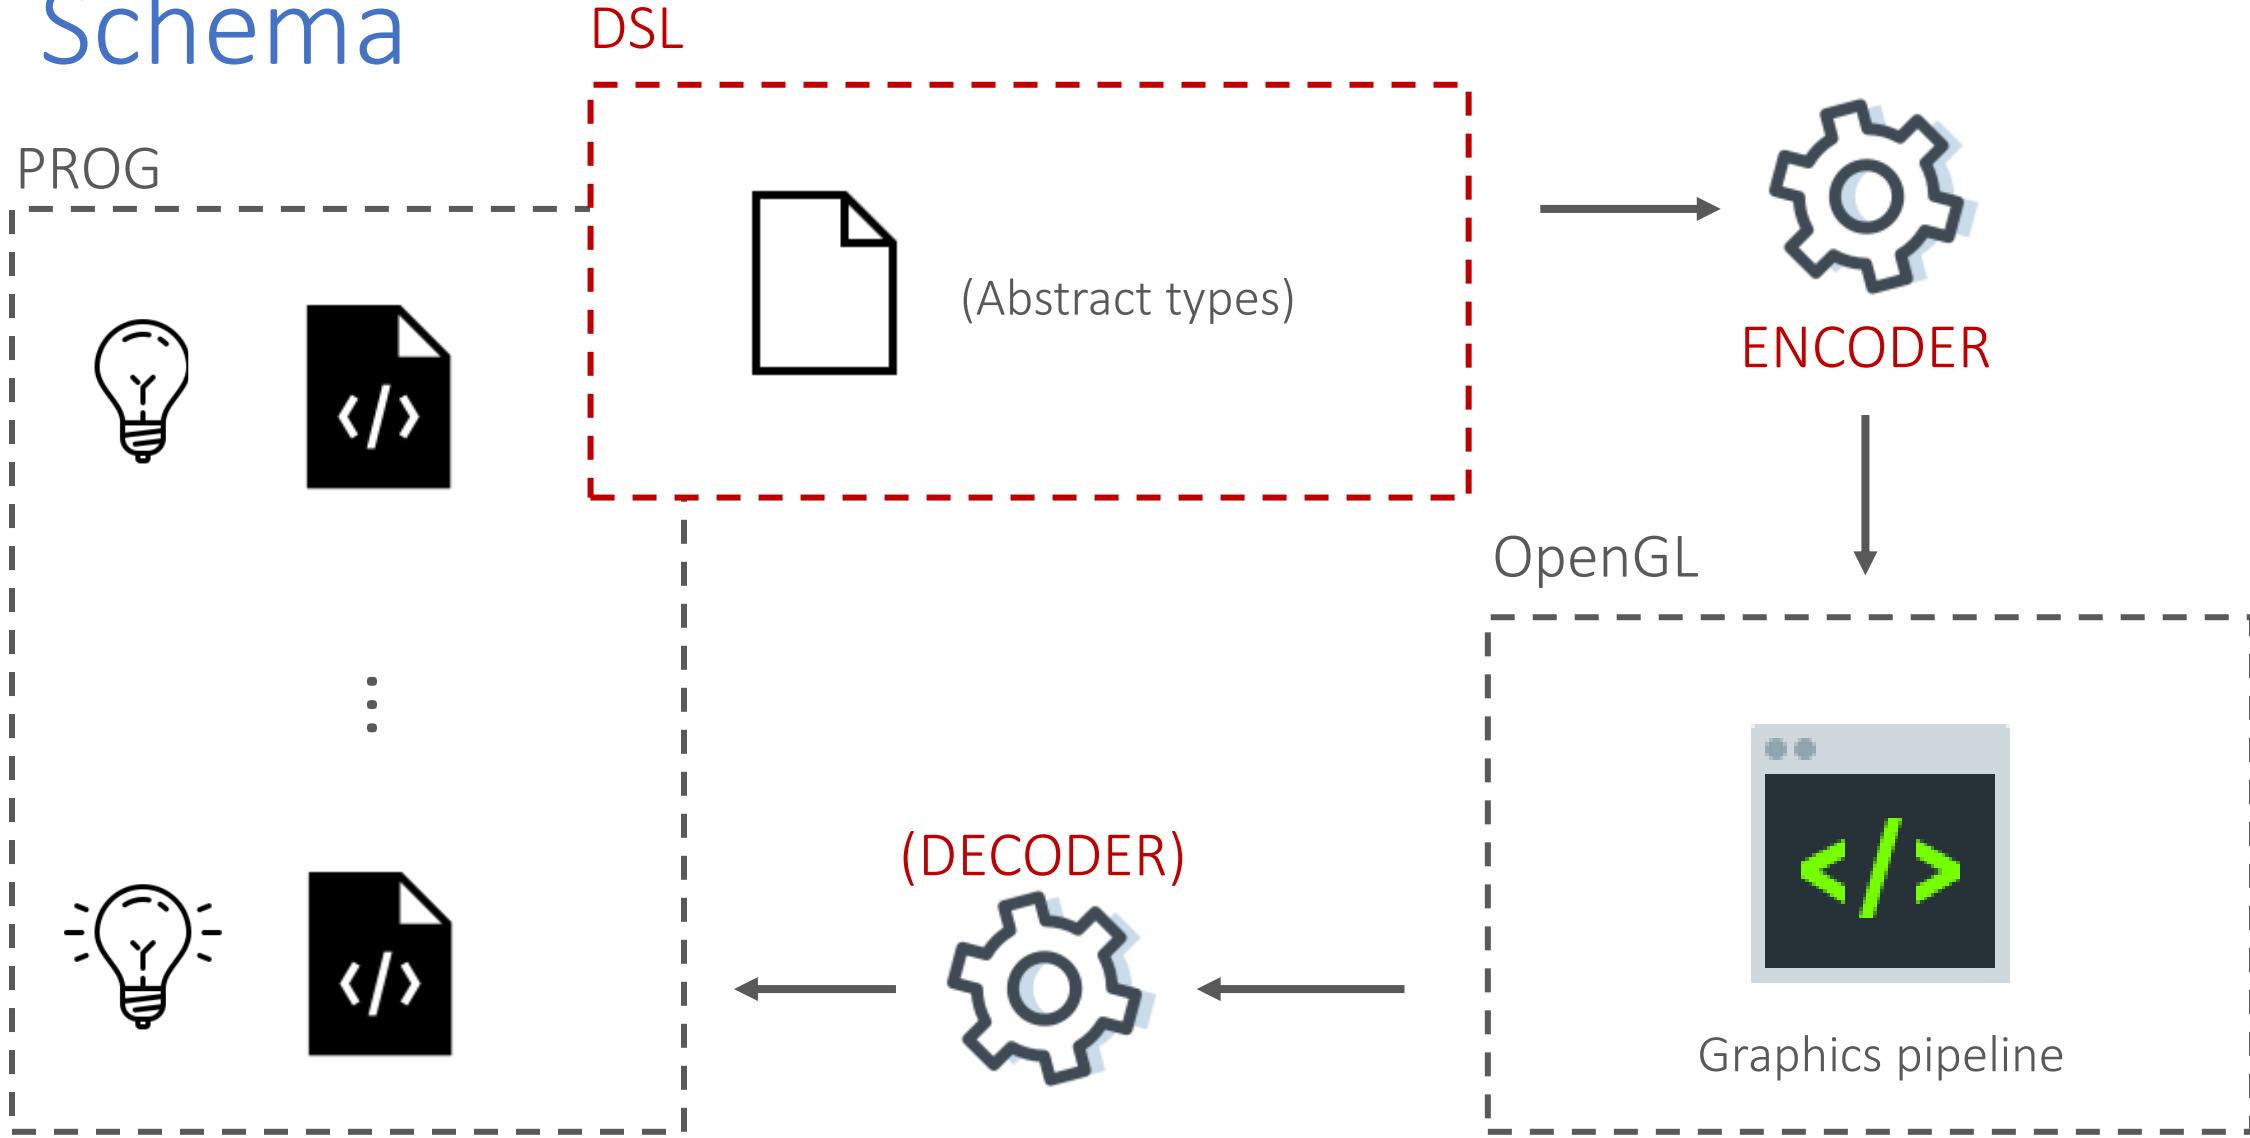

This translation can then be evaluated by the graphics pipeline of OpenGL

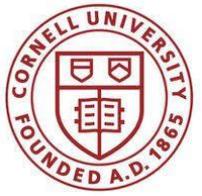

( Then a decoder allows us to get the results with the desired abstract types )

# Schema

# Gator

Language created by *Dietrich Geisler, Irene Yoon, Aditi Kabra, Horace He, Yinnon Sanders & Adrian Sampson*

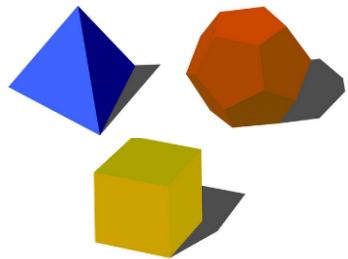

Higher level programming model that allows focus on the geometric semantics of programs

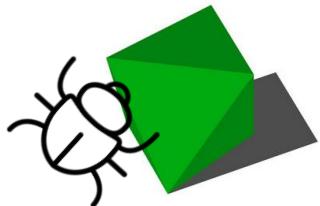

Gator is a **surface language** with an extended type system  
based on a **target language** with a type set (GLSL)  
A type-directed translation allows to compile Gator to GLSL

# Problem & ideas

3D scenes consist of many individual objects & the rendering code must combine vectors of different coordinate systems

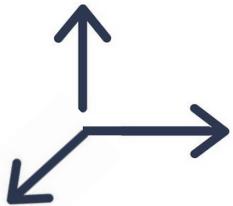

Geometry bugs are difficult to detect

Introduce a type system to eliminate this class of bugs & implement a mechanism that can exclude some bugs by construction

# A geometry type

“Geometry types describe the coordinate system representing each value and the transformations that manipulate them”

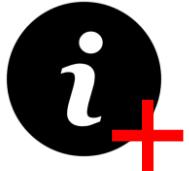

A geometry type is made up of 3 components:

- Reference frame
- Geometric object
- Coordinate scheme

Define which operations are legal

# Syntax

Geometry types give more information about the objects they represent than simple vector types in GLSL

Syntax for a geometry type is *scheme*<*frame*>.object

Example:

cart3<world>.point

represents the type of a point in world space represented in a 3D cartesian coordinate scheme

# Example: Diffuse Lighting

GLSL implementation

```
float naiveDiffuse(vec3 lightPos, vec3 fragPos, vec3 fragNorm) {  
    vec3 lightDir = normalize(lightPos - fragPos);  
    return max(dot(lightDir, normalize(fragNorm)), 0.);  
}
```

lightPos & fragPos have the same type but they are not geometrically compatible  
We have different vectors in different coordinate systems

Subtraction between fragPos (model space) & lightPos (world space)

## GLSL implementation (Cont.)

```
float naiveDiffuse(vec3 lightPos, vec3 fragPos, vec3 fragNorm) {  
    vec3 lightDir = normalize(lightPos - uModel * fragPos));  
    return max(dot(lightDir, normalize(fragNorm)), 0.);  
}
```

To correct the problem we transform the two vectors into a common coordinate system

We define a transformation matrix to go from model to world space

## GLSL implementation (Cont.)

```
float naiveDiffuse(vec3 lightPos, vec3 fragPos, vec3 fragNorm) {
    vec3 lightDir = normalize(lightPos - vec3(uModel * vec4(fragPos, 1.)));
    return max(dot(lightDir, normalize(fragNorm)), 0.);
}
```

3x3 Cartesian transformation matrices allow only linear transformations

4x4 transformation matrices in Homogeneous coordinates can express affine transformations

Cartesian to Homogeneous:  $[x, y, z] \rightarrow [x, y, z, 1.]$

Homogeneous to Cartesian:  $[x, y, z, w] \rightarrow [x/w, y/w, z/w]$

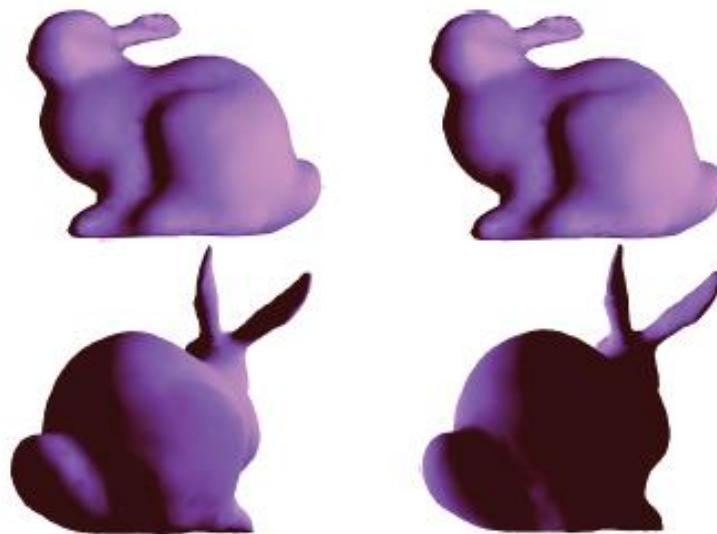

## GLSL implementation (Cont.)

```
float naiveDiffuse(vec3 lightPos, vec3 fragPos, vec3 fragNorm) {  
    vec3 lightDir = normalize(lightPos - vec3(uModel * vec4(fragPos, 1.)));  
    return max(dot(lightDir, normalize(vec3(uModel * vec4(fragNorm, 0.)))));  
}
```

The final calculation of the diffuse intensity

We must transform now fragNorm into world space  
It's a direction so w should be 0

## GLSL implementation (Cont.)

(a) Correct implementation. (b) With geometry bug.

Subtle differences can imply errors

```
frame model has dimension 3;  
frame world has dimension 3;
```

## Gator implementation

```
float diffuseNaive(  
    cart3<world>.point lightPos,  
    cart3<model>.point fragPos,  
    cart3<model>.direction fragNorm) {  
    cart3<world>.direction lightDir = normalize(lightPos - fragPos);  
    return max(dot(lightDir, normalize(fragNorm)), 0.0);  
}
```

lightPos & fragPos are both positions but their reference frames  
are different : <world> vs <model>

The subtraction implies an error

## Gator implementation (Cont.)

```
with frame(3) r:  
coordinate cart3 : geometry {  
    object vector is float[3];  
    ...  
}
```

```
float diffuse(  
    cart3<world>.point lightPos,  
    cart3<model>.point fragPos,  
    cart3<model>.direction fragNorm,  
    hom3<model>.transformation<world> uModel) {  
    cart3<world>.direction lightDir =  
        normalize(lightPos - (uModel * fragPos));  
    return max(dot(lightDir, normalize(uModel * fragNorm)), 0.0);
```

We need to define an affine transformation matrix to transform  
fragPos & fragNorm into world reference frame

Multiplying uModel & fragPos implies an error because the coordinate schemes are different

## Gator implementation (Cont.)

```
float diffuse(
    cart3<world>.point lightPos,
    cart3<model>.point fragPos,
    cart3<model>.direction fragNorm,
    hom3<model>.transformation<world> uModel) {
    cart3<world>.direction lightDir =
        normalize(lightPos - reduce(uModel * homify(fragPos)));
    return max(dot(lightDir, normalize(reduce(uModel * homify(fragNorm)))), 0.0);
}
```

```
coordinate hom3 : geometry {
    object point is float[4];
    object direction is float[4];
    with frame(3) r:
        object transformation is float[4][4];
    ...
}
```

homify() allows us to go from `cart3<model>.point` to `hom3<model>.point` ( $w=1$ )  
or to go from `cart3<model>.direction` to `hom3<model>.direction` ( $w=0$ )

`reduce()` allows to map Homogeneous to Cartesian coordinates

# Subtyping in Gator

Object & type declarations extend existing types

All types must be given a supertype which can be a primitive type (**bool**, **int**, **float**, **string**, **array**) or a geometry type

Example:

```
type angle is float;  
type acute is angle;  
type obtuse is angle;
```

Subtype of float

Subtype of angle

# Conclusion

The Gator type system avoids statically incorrect coordinate system transformation codes

We can thus automatically generate a correct transformation code by construction

- Programmers do not write vector-matrix multiplication calculations
  - Let the compiler find the right transformations

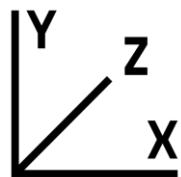

Gator helps to limit the number of geometry bugs

# Limitations

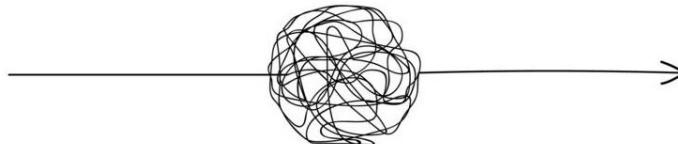

The created abstraction remains low level

It's only based on coordinate system transformations

The syntax is a bit complicated

# Inspiration

The notion of surface language

New types based on primitives

color, light, texture, normal, (position)

A little less complicated syntax

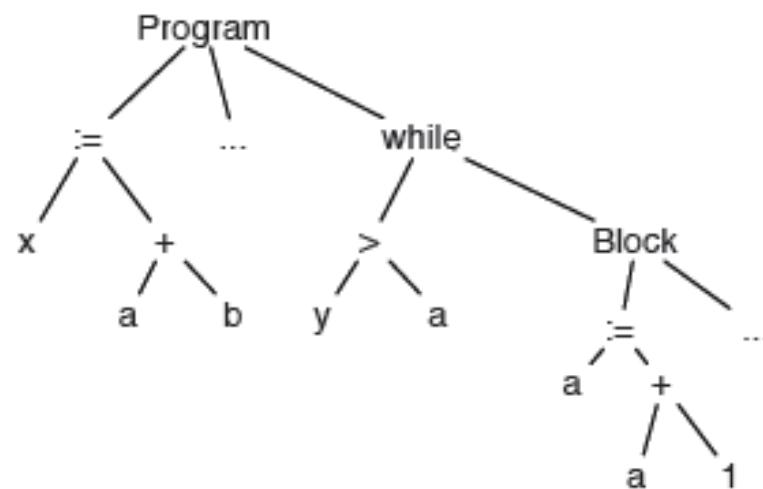

# Abstract Syntax Tree (AST)

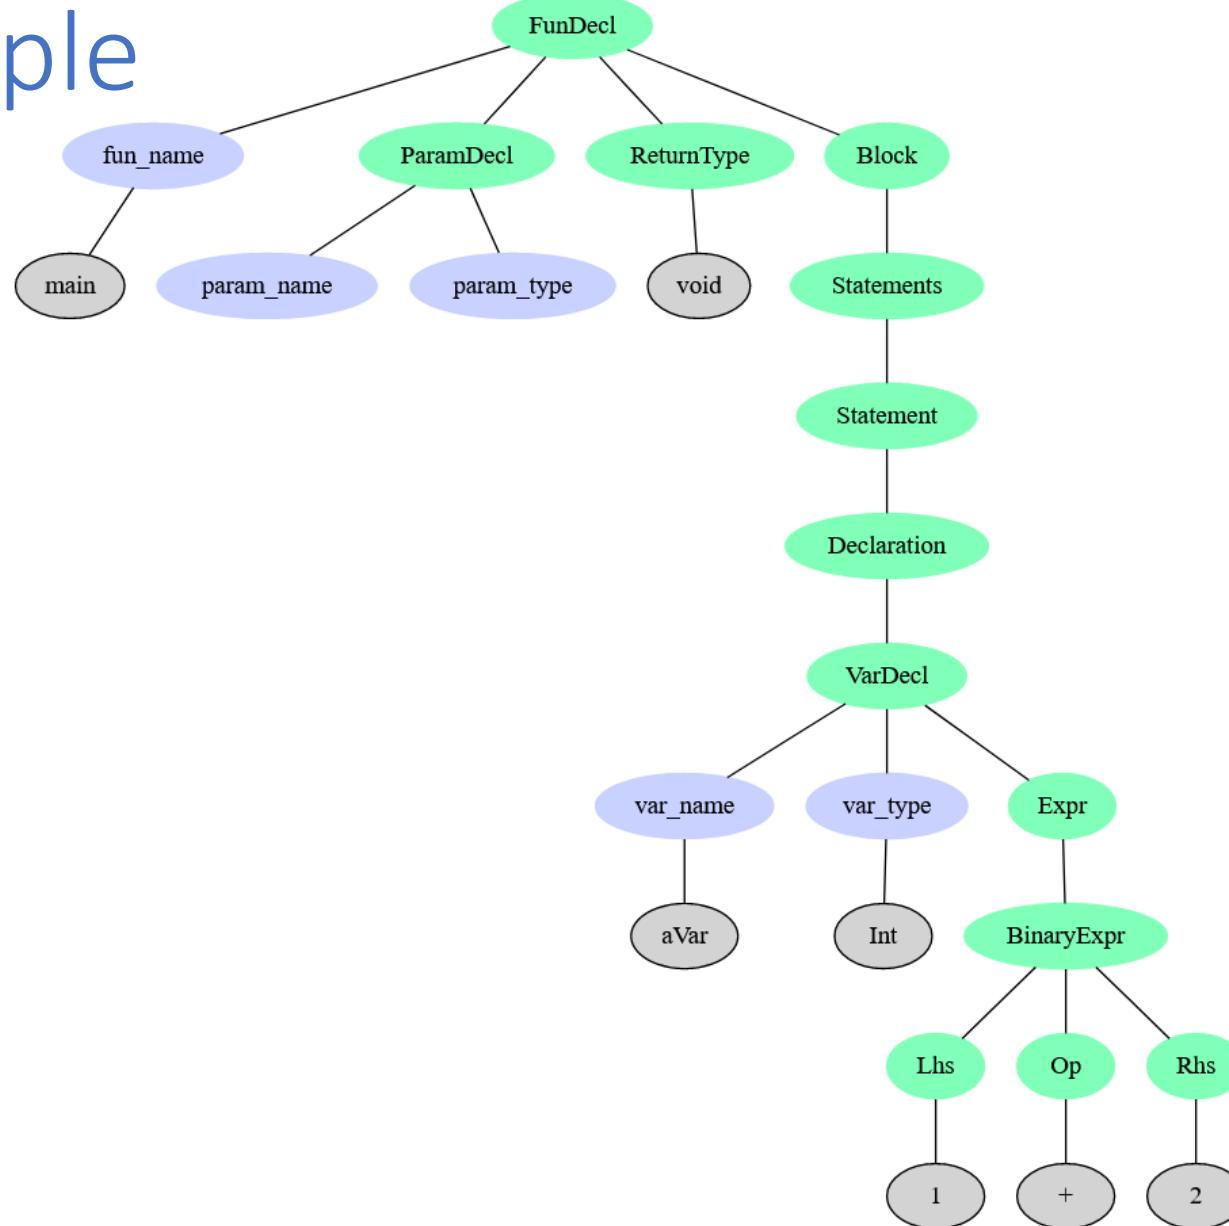

Tree in which, internal nodes are marked by operators  
and where external ones represent the operands

Example:

```
x := a + b;  
y := a * b;  
while (y > a) {  
    a := a + 1;  
    x := a + b  
}
```

# AST example

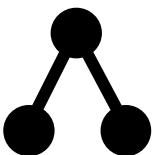

# Some tools

## Swift-AST-Explorer

Only supports Swift language

Structure representation with pop-up details  
for each element of the code

## AST-Explorer

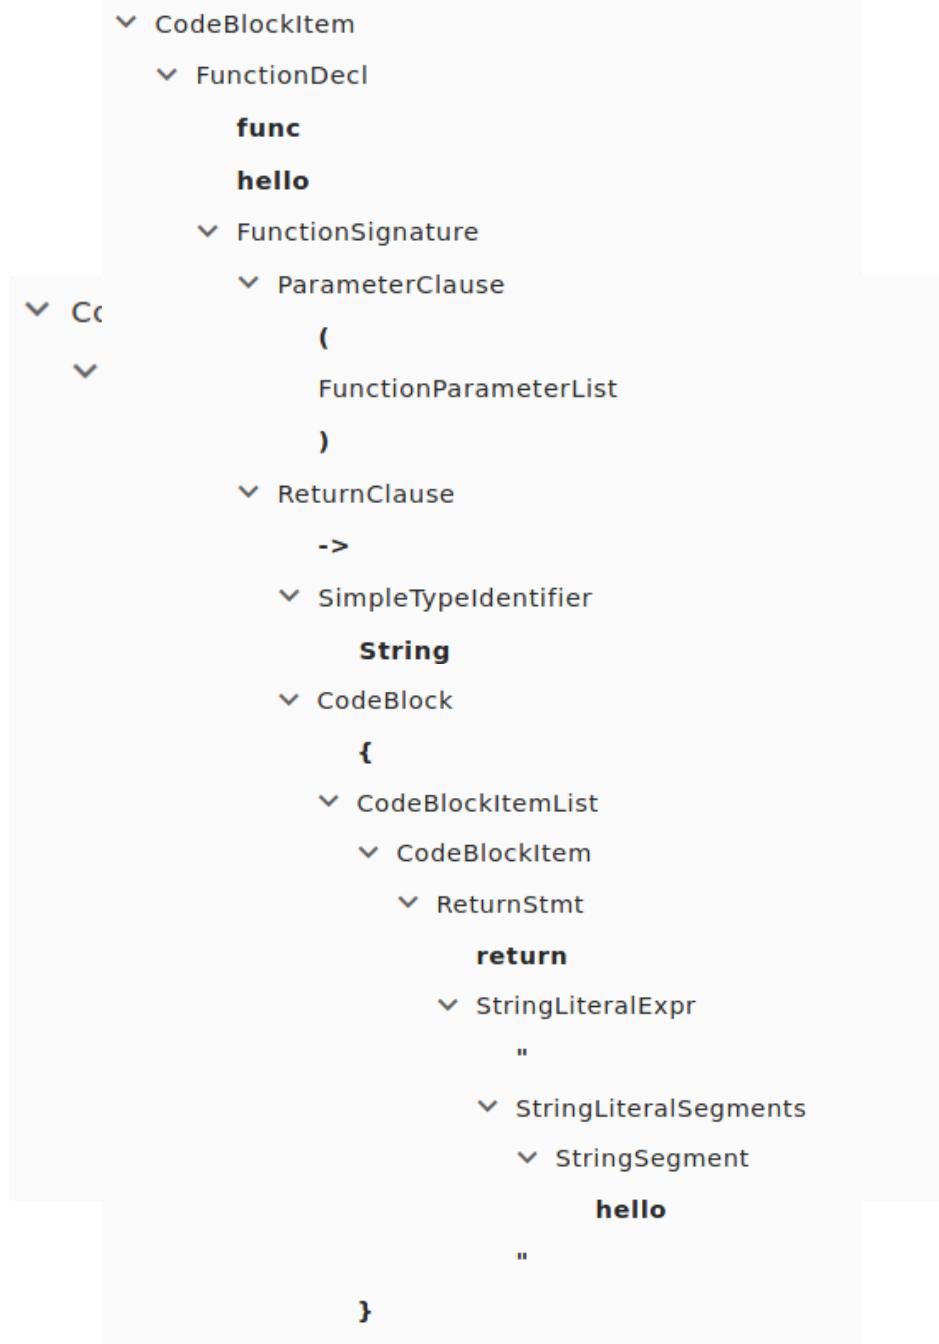

Supports a lot of languages like Java, HTML, Python, ... & GLSL

Tree or JSON representation

# Examples

Swift-AST-Explorer

```
1 import Foundation
2
3 let num: Int = 5
4
5 func hello() -> String {
6     return "hello"
7 }
```

# Examples (Cont.)

AST-Explorer

```
1 varying vec3 ourColor;  
2  
3 void main() {  
4     FragColor = vec4(ourColor, 1.0f);  
5 }  
6
```

# DynaSOAr

Here, we will be based on the idea of DynaSOAr

Which is an object-oriented language for manipulating objects

# General idea

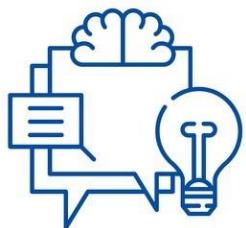

We want to have the perfect language for our use-cases

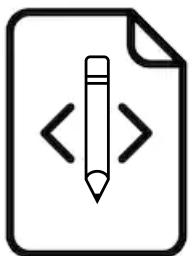

We want to have high-level objects that can be handled in a simple way

# Development

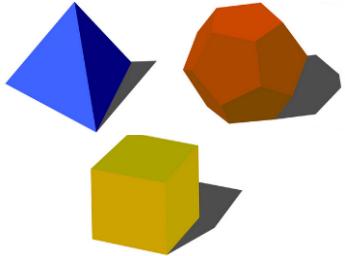

First, we must define our language and the concepts we want

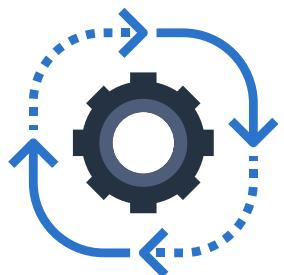

Then, we must specify the syntax of this language

# Concepts

## Use-cases

Our needs are to write graphics applications  
in which we manipulate 3D objects

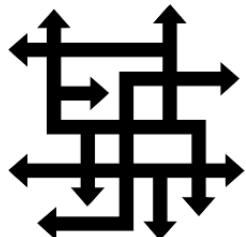

We want to call methods on them, do calculations, etc.

# Concepts

## Limitations

Here, we want to define everything that it would be possible to do for users ...

... but it's complicated to be complete

# Concepts

The abstractions that we need to write an application with 3D objects are:

The position of the objects

The type of the objects

The color of the objects

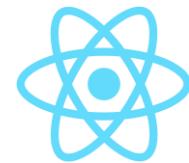

The operations linked to these objects

The physics of the objects

# Declarative Language

We are moving towards a **declarative** language inspired by React

React is based on the notions of:

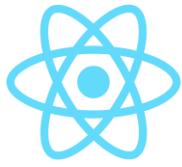

Components, Properties and States

Render function, Update functions

# React - Component

The component system allows us to consider each piece of code independently

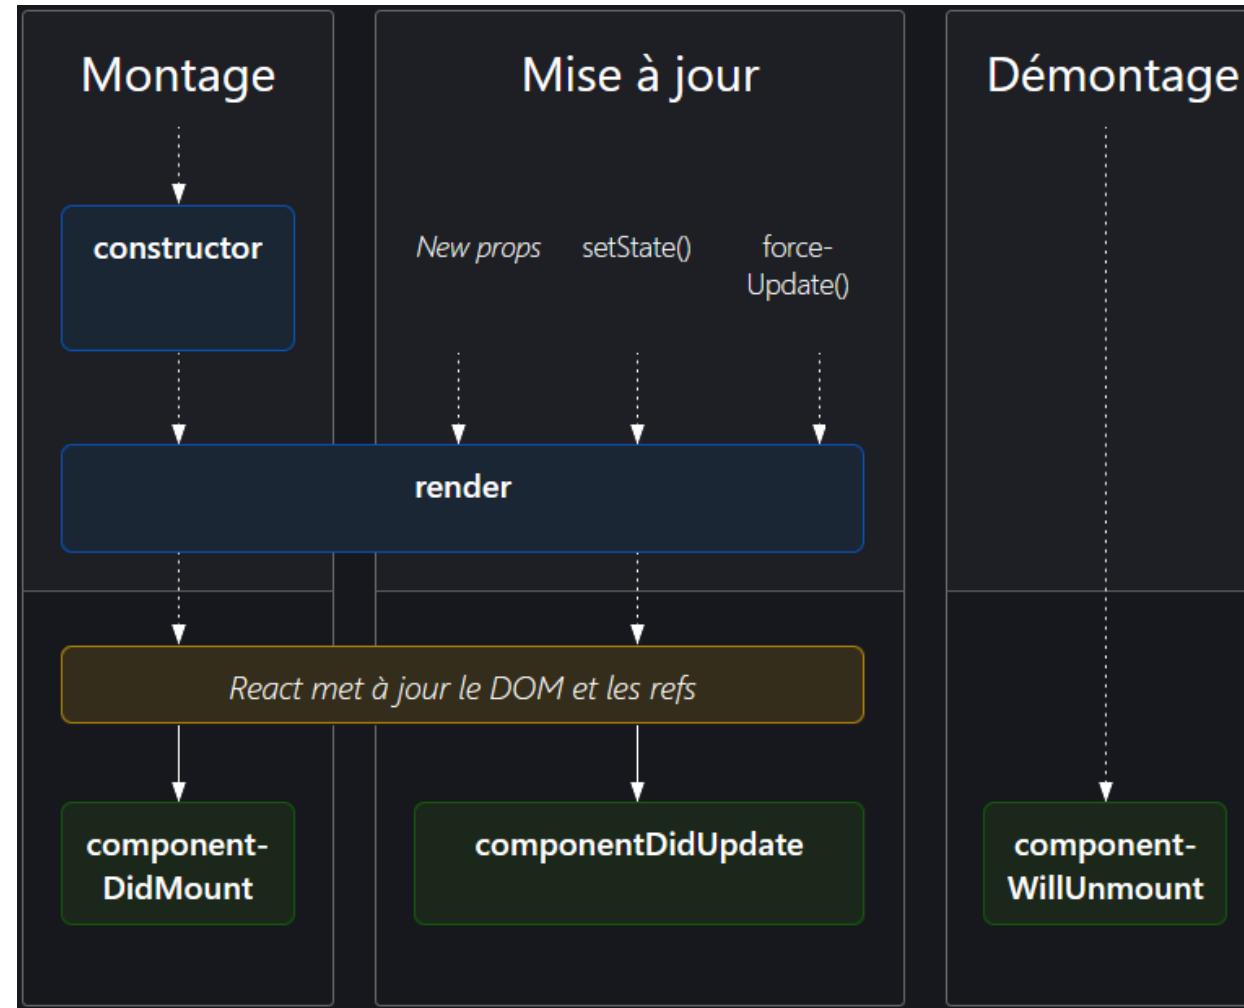

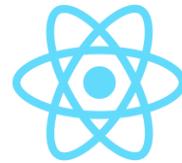

We can then combine different components to get something more complex

Example:

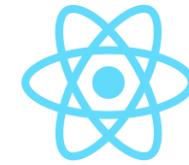

```
function Welcome(props) {
  return <h1>Bonjour, {props.name}</h1>;
}
```

```
class Welcome extends React.Component {
  render() {
    return <h1>Bonjour, {this.props.name}</h1>;
  }
}
```

# React - Life cycle

# React - Constructor, Props & State

`this.props` contains the properties defined by the caller of the component

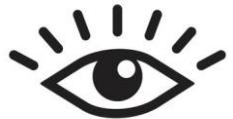

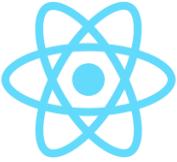

A component should never modify its own properties

Local state contains component-specific data, which may change over time

To modify the local state of a component we use `setState()`

# React - Render()

The render() method takes data as input and returns what should be displayed.

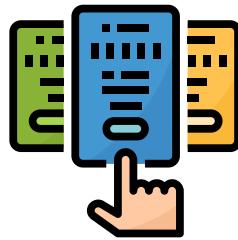

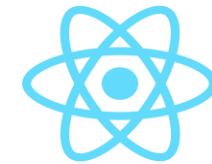

When the local state of a component changes, its display is updated by calling render()

We use a tick() function to update every second / frame

# React - componentDidMount() & componentDidUpdate()

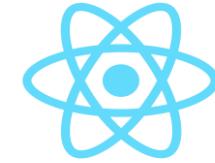

componentDidMount() is called immediately after  
the component is mounted

This is where we make the subscriptions

componentDidUpdate() is called immediately after  
the update has taken place.

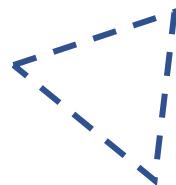

# React - componentWillMount()

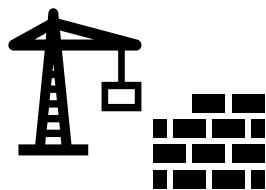

componentWillUnmount() is called immediately before  
a component is unmounted

Here we delete the subscriptions made in componentDidMount()

# Idea for our language

We give some basic geometric shapes

The idea is to use the notion of **mesh (primitive)**, which is a complete object, composed of several shapes

Example:

A cube is a particular mesh constructed with two triangles per face

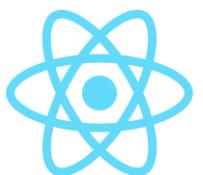

# Syntax

We define in the syntax how we would like to define and manipulate the objects

Our goal is to have a simple and meaningful syntax

The syntax will be based on React

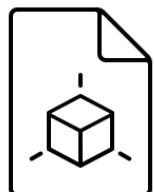

# React to our language

We use this notion of components to declare and define a geometric object

We use the same principle of global state, property, and render function

Use of the tick function to update every second / frame

# Components (highest level)

Defines the global state of the application  
⚠ It is only used in the highest component

Component declaration

```
Component <name_component> {  
  
    var state: [String: AnyObject] = [:]  
  
    init() {  
        self.state = ["key": value,  
                    ...]  
    }  
  
    var <var_name> = <value>  
  
    function <function_name>([<arg_name>: <type>]) -> <return_type> {  
        <body>  
        return <return_value>  
    }  
}
```

Variables or constants  
declaration

A way to sub and unsub to Tick()

Declares the functions relating to the component

# Components (highest level)

Tick() function declaration

Function given in the standard library  
to update the global state

```
function tick() {  
    state = updateState(lastState: state,  
                        newState: ["key": value,  
                                   ...]  
    )  
}  
  
function render() {  
    return (  
        <container>  
  
        <><component_name> ([<arg_name>=value])</>  
  
        </container>  
    )  
}
```

Component rendering function

# Components (lowest level)

Component declaration

```
Component <name_component> {  
    init() {  
        super.init()  
    }  
  
    var <var_name> = <value>  
  
    function <function_name>([<arg_name>: <type>]) -> <return_type> {  
        <body>  
        return <return_value>  
    }  
}
```

Get the properties passed to  
the component

# Components (lowest level)

Component rendering  
function

```
function render() {  
  return (  
  
    <mesh type= <value>  
      position= <value>  
      properties= [<value>] />  
  
  )  
}
```

Call a subcomponent or  
render a mesh to graphically represent an object

⚠ Render a mesh is never in the  
highest component

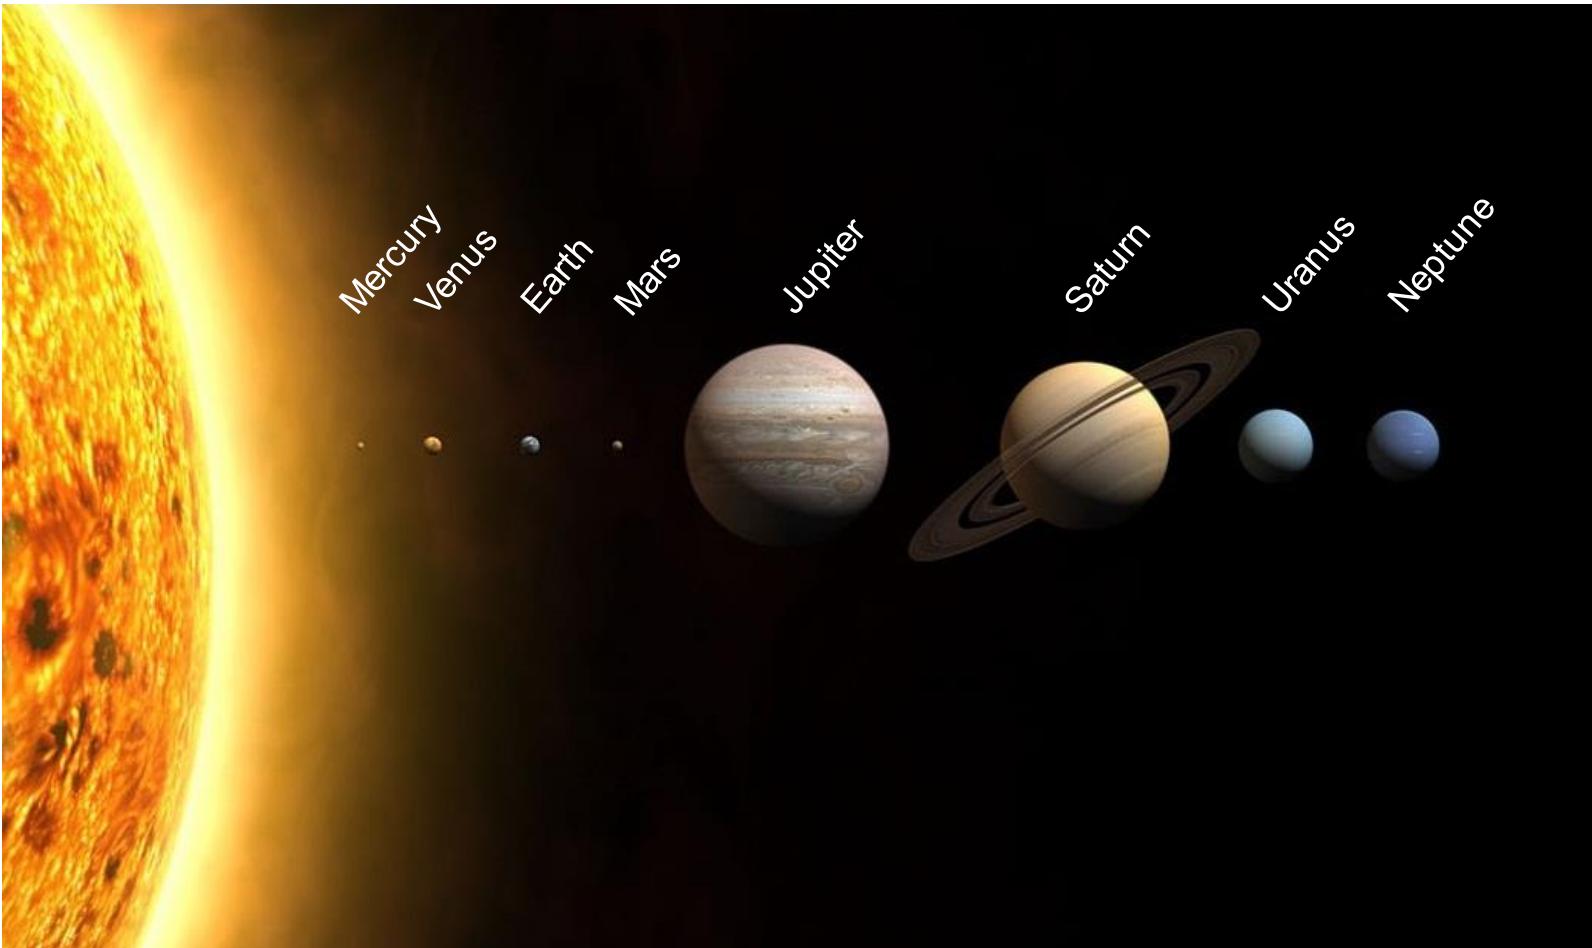

# Entry point

Users can define their own types in addition to what is given in the standard library

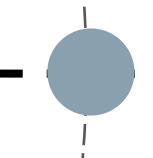

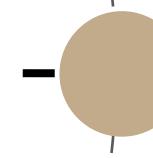

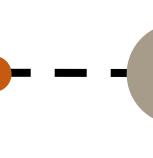

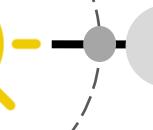

```
structure <name_structure> {  
    var <var_name>: <type>  
    ...  
  
    init(<args>) {  
        ...  
  
        function <function_name>([<arg_name>: <type>]) -> <return_type> {  
            <body>  
            return <return_value>  
        }  
    }  
  
    <><highest_level_component> ()>
```

Then, we specify the top-level component

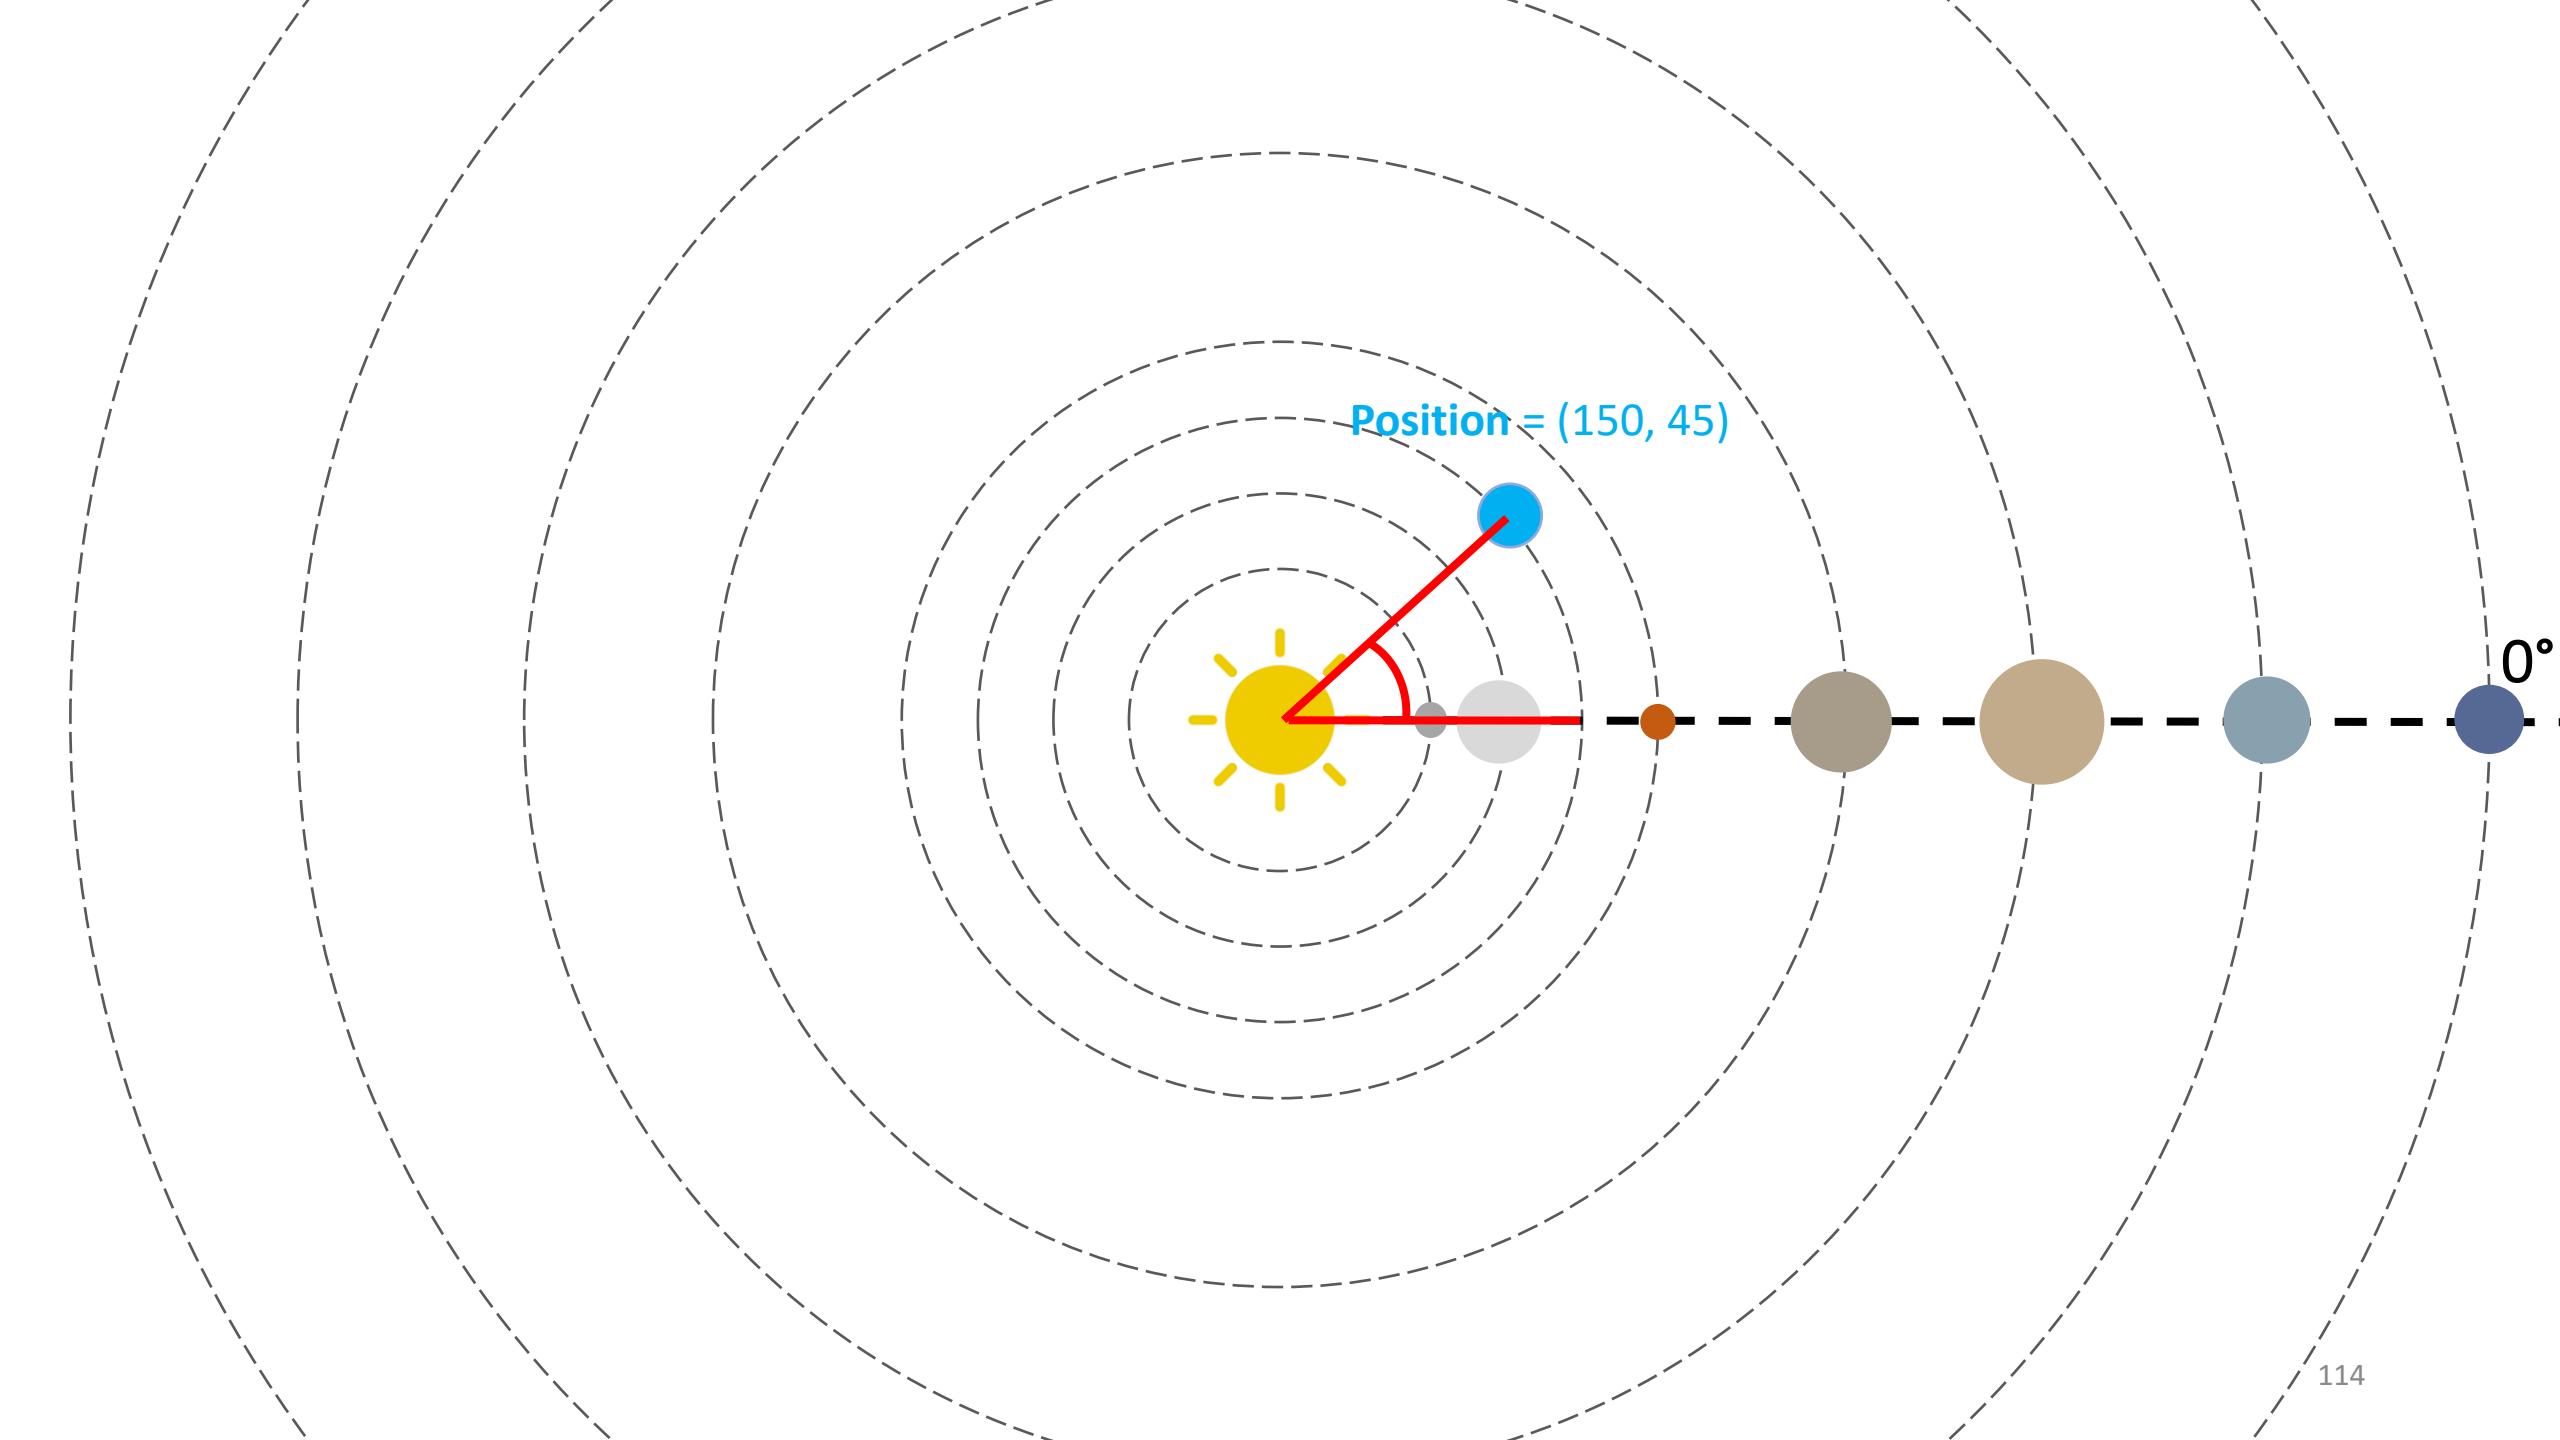

# Example - Solar system

**Position = (sun distance, polar angle)**

$0^\circ$

A diagram illustrating the positions of celestial bodies relative to the Sun. The Sun is represented by a yellow circle with radiating lines. A blue circle, labeled "Position = (150, 45)", is shown in its orbit. A grey circle is also visible. A red arrow points from the Sun to the blue circle, indicating its position. To the right, a series of dashed circles represent other orbits. A horizontal dashed line extends from the Sun through several grey dots, which are labeled with numbers: 0°, 114, and 114 again. The background consists of dashed elliptical orbits.

0°

Position = (150, 45)

```
Component SystemSolar {  
  
    var state: [String: AnyObject] = [:]  
  
    init() {  
        self.state = ["solarCoord": Coord(polar: (0, Angle(deg: 0))), "solarRevo": 0, "solarRadius": 696340,  
                    "mercuryCoord": Coord(polar: (58, Angle(deg: 0))), "mercuryRevo": 88, "mercuryRadius": 2440,  
                    "venusCoord": Coord(polar: (108, Angle(deg: 0))), "venusRevo": 225, "venusRadius": 6050,  
                    "earthCoord": Coord(polar: (150, Angle(deg: 0))), "earthRevo": 365, "earthRadius": 6370,  
                    "marsCoord": Coord(polar: (228, Angle(deg: 0))), "marsRevo": 687, "marsRadius": 3390,  
                    "jupiterCoord": Coord(polar: (779, Angle(deg: 0))), "jupiterRevo": 4380, "jupiterRadius": 69910,  
                    "saturnCoord": Coord(polar: (1434, Angle(deg: 0))), "saturnRevo": 10585, "saturnRadius": 58230,  
                    "uranusCoord": Coord(polar: (2871, Angle(deg: 0))), "uranusRevo": 30660, "uranusRadius": 25360,  
                    "neptuneCoord": Coord(polar: (4495, Angle(deg: 0))), "neptuneRevo": 60225, "neptuneRadius": 24600  
                ]  
    }  
}
```

*solarSystem.plist*

The application has a **global state** which contains all the information  
It is defined in the highest-level component

```

structure Angle {
    var deg: Double
    var rad: Double

    init(deg: Double = nil, rad: Double = nil) {
        self.deg = deg
        self.rad = rad
    }

    function degToRad() -> Double {
        return (deg * (pi/180))
    }

    function radToDeg() -> Double {
        return (rad * (180/pi))
    }
}

```

*bibli.patl*

```

structure Coord {

                                                Angle(deg: this.updatePlanetPos(currentAngle: state["earthCoord"].polar[1],
                                                                 revolution: state["earthRevo"])))),,
                  ...
        ]
    )
}
```

*solarSystem.patl*

```
function updateState(lastState: [String: AnyObject], newState: [String: AnyObject]) -> [String: AnyObject] {
    for key in newState {
        lastState[key] = newState[key]
    }
    return lastState
}
```

*bibli.patl*

```
function render() {
  return (
    <container>
      <Sphere (name="Solar", pos={state["solarCoord"]}, radius={state["solarRadius"]})/>
      <Sphere (name="Mercury", pos={state["mercuryCoord"]}, radius={state["mercuryRadius"]})/>
      <Sphere (name="Venus", pos={state["venusCoord"]}, radius={state["venusRadius"]})/>
      <Sphere (name="Earth", pos={state["earthCoord"]}, radius={state["earthRadius"]})/>

      ...
    </container>
  );
}
```

*solarSystem.patl*

```
Component Sphere {
    init() {
        super.init()
    }

    let meshPosition = pos.polarToCart()

    function render() {
        return (
            <mesh type="sphere"
                position={meshPosition}
                properties={[radius]}/>
        )
    }
}
```

*solarSystem.patl*

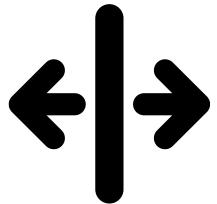

Local states are avoided in low-level components

We get the information with `super.init()`

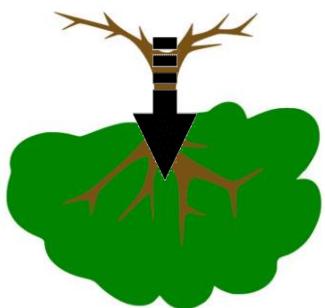

```
// Entry point  
<SystemSolar ()/>
```

*solarSystem.pat*

# In summary

The application state is separated from the rendering (graphic representation)

All properties descend from the highest component to the lowest component

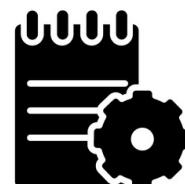

# Recall: Embedded DSL

The idea is to use Swift as the host language

This implies making some sacrifices on the syntax of our language ...

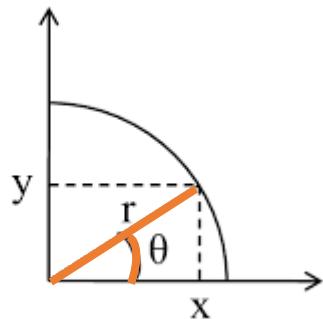

... but allows us to use the swift compiler

# Example - Solar system: Using Swift

```
class SystemSolar {
    var state: Dictionary<String, Any> = [:]
    var callTick: Bool = true

    init() {
        self.state = ["solarCoord": Coord(polar: (0, Angle(deg: 0))), "solarRevo": 0.0, "solarRadius": 696340.0,
                      "mercuryCoord": Coord(polar: (58, Angle(deg: 0))), "mercuryRevo": 88.0, "mercuryRadius": 2440.0,
                      "venusCoord": Coord(polar: (108, Angle(deg: 0))), "venusRevo": 225.0, "venusRadius": 6050.0,
                      "earthCoord": Coord(polar: (150, Angle(deg: 0))), "earthRevo": 365.0, "earthRadius": 6370.0,
                      "marsCoord": Coord(polar: (228, Angle(deg: 0))), "marsRevo": 687.0, "marsRadius": 3390.0,
                      "jupiterCoord": Coord(polar: (779, Angle(deg: 0))), "jupiterRevo": 4380.0, "jupiterRadius": 69910.0,
                      "saturnCoord": Coord(polar: (1434, Angle(deg: 0))), "saturnRevo": 10585.0, "saturnRadius": 58230.0,
                      "uranusCoord": Coord(polar: (2871, Angle(deg: 0))), "uranusRevo": 30660.0, "uranusRadius": 25360.0,
                      "neptuneCoord": Coord(polar: (4495, Angle(deg: 0))), "neptuneRevo": 60225.0, "neptuneRadius": 24600.0
                    ]
        self.subTick(interval: 1)
    }
}
```

main.swift

```
"solarCoord": Coord(polar: (0, Angle(deg: 0)))
```

*main.patl*

```
struct Coord {
    var polar: (Double, Angle)?
    var cart: (Double, Double)?
}

init(polar: (Double, Angle)? = nil, cart: (Double, Double)? = nil) {
    self.polar = polar
    self.cart = cart
}

func polarToCart() -> (Double, Double) {
    let x = polar!.0 * cos(polar!.1.deg!)
    let y = polar!.0 * sin(polar!.1.deg!)
    return (x,y)
}

func cartToPolar() -> (Double, Angle) {
    let r = sqrt(pow(cart!.0, 2.0) + pow(cart!.1, 2.0))
    let t = Angle(deg: atan(cart!.1 / cart!.0))
    return (r,t)
}
```

*bibli.patl*

```
"solarCoord": Coord(polar: (0, Angle(deg: 0)))
```

*main.patl*

```

*main.patl*

# Syntax decoration

So, to get a different syntax from Swift we will go through:

The definition of custom operators

The creation of a template language to define our own keywords

# Formalization

UN/SUBSCRIPTIONS

RENDER

COMPONENT\_LOWLEVEL

(PROPS)

INIT

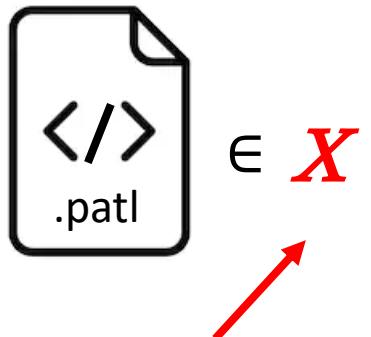

RENDER

COMPONENT\_LOWLEVEL | MESH

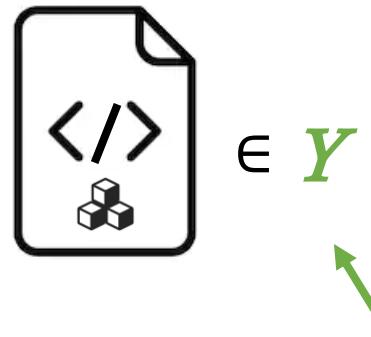

# Static typing semantics

GLOBAL\_SYSTEM

$$h : X \rightarrow Y$$

$\in X$

$\in Y$

Set of .patl programs which are built with the concept of components top/low level

Set of Rendery programs composed of sequences of Rendery (Swift) instruction

# Static typing semantics

COMPONENT\_TOPLEVEL

Can be considered as a 4-tuple:

( name , state , tick , render\_top )

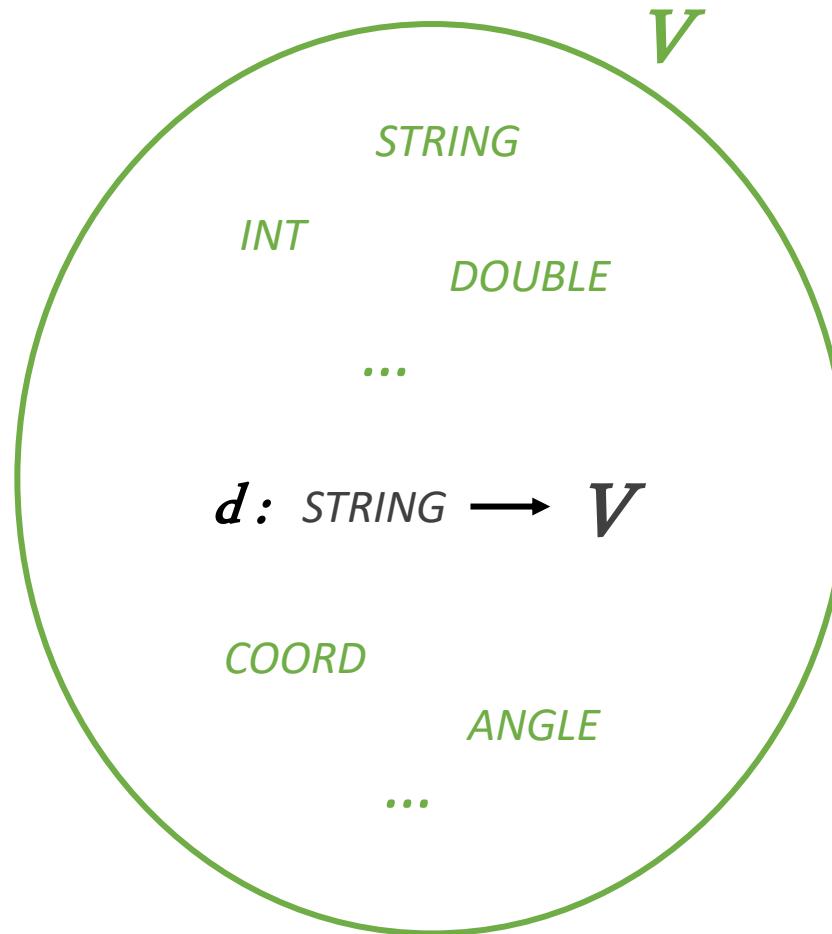

name  $\in$  STRING

# Static typing semantics

state  $\in V$

Where  $V$  is a set of some elements:

- Several primitives
- Dictionaries
- Abstract objects

# Static typing semantics

`render_top`  $\in \textcolor{violet}{RT}$

Where  $\textcolor{violet}{RT}$  is a set of partial function :  $\textcolor{violet}{rt} : \textcolor{violet}{V} \rightarrow (\textcolor{violet}{STRING} \times \textcolor{violet}{P} \times \textcolor{violet}{RL})^*$

A `COMPONENT_LOWLEVEL` can be considered as a 3-tuple:

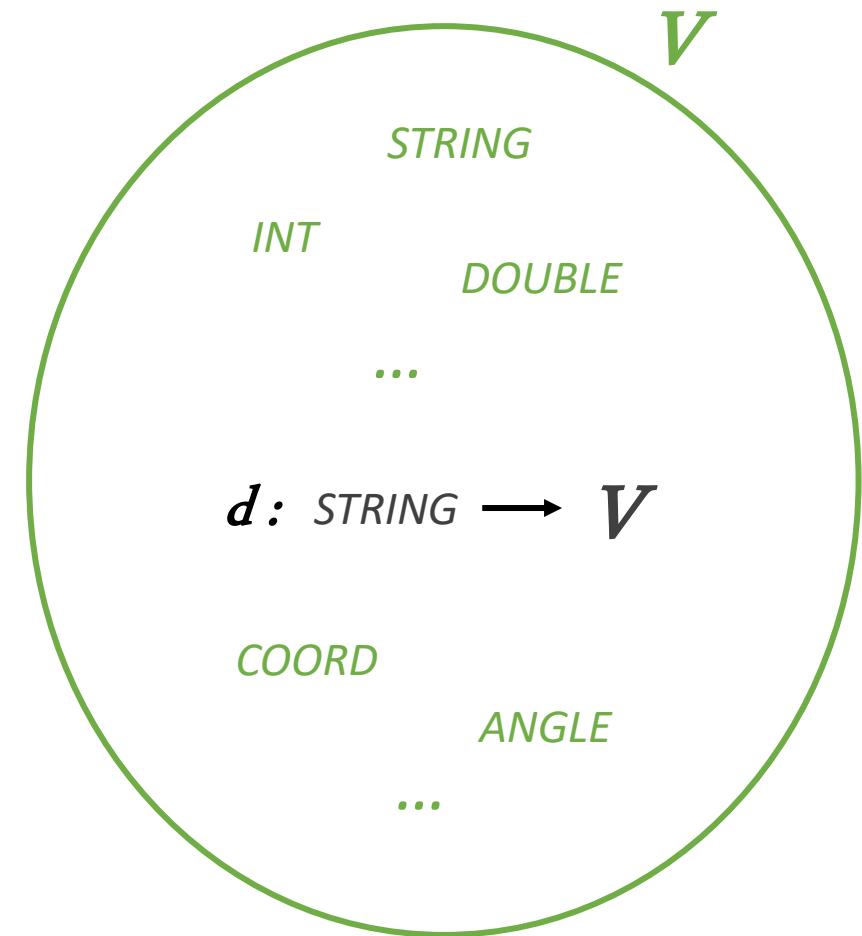

( `name` , `props` , `render_low` )

`name`  $\in \textcolor{violet}{STRING}$

# Static typing semantics

props  $\in P$

Where  $P$  is a set of partial function :  $p: STRING \rightarrow V$

# Static typing semantics

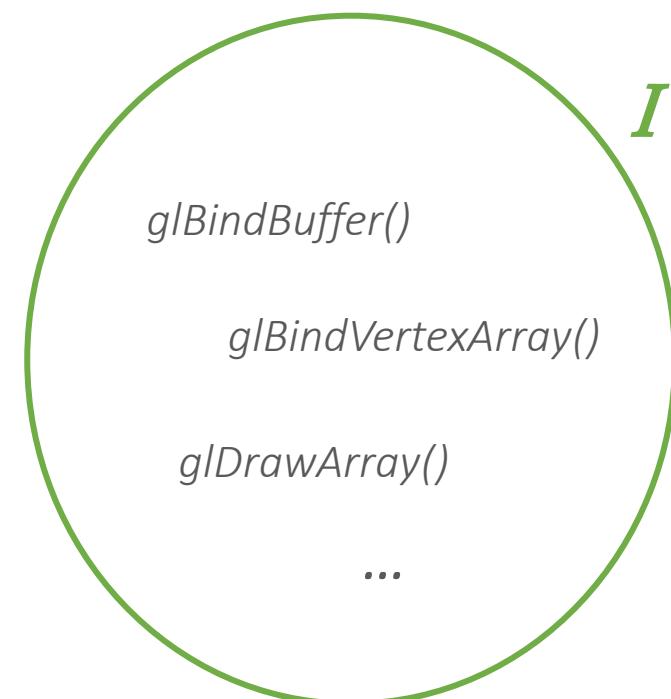

`render_low`  $\in \textcolor{violet}{RL}$

Where  $\textcolor{violet}{RL}$  is a set of partial function :  $\textcolor{violet}{rl}: P \rightarrow ((\textcolor{violet}{STRING} \times P \times \textcolor{violet}{RL}) \cup \textcolor{violet}{M})^*$

`MESH`  $\in \textcolor{violet}{M}$

Where  $\textcolor{violet}{M}$  is a set of partial function :  $\textcolor{violet}{m}: P \rightarrow \textcolor{violet}{I}$

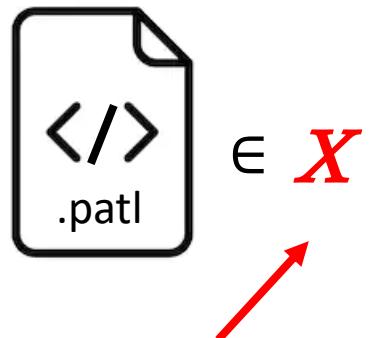

$\textcolor{violet}{I}$  is a set of OpenGL instructions

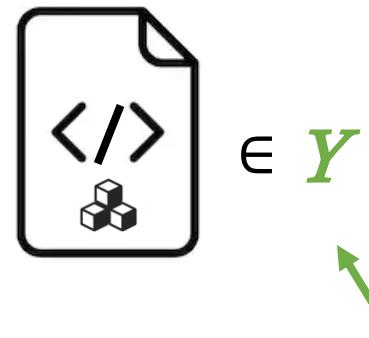

# Static typing semantics

GLOBAL\_SYSTEM

$$h : X \rightarrow Y$$

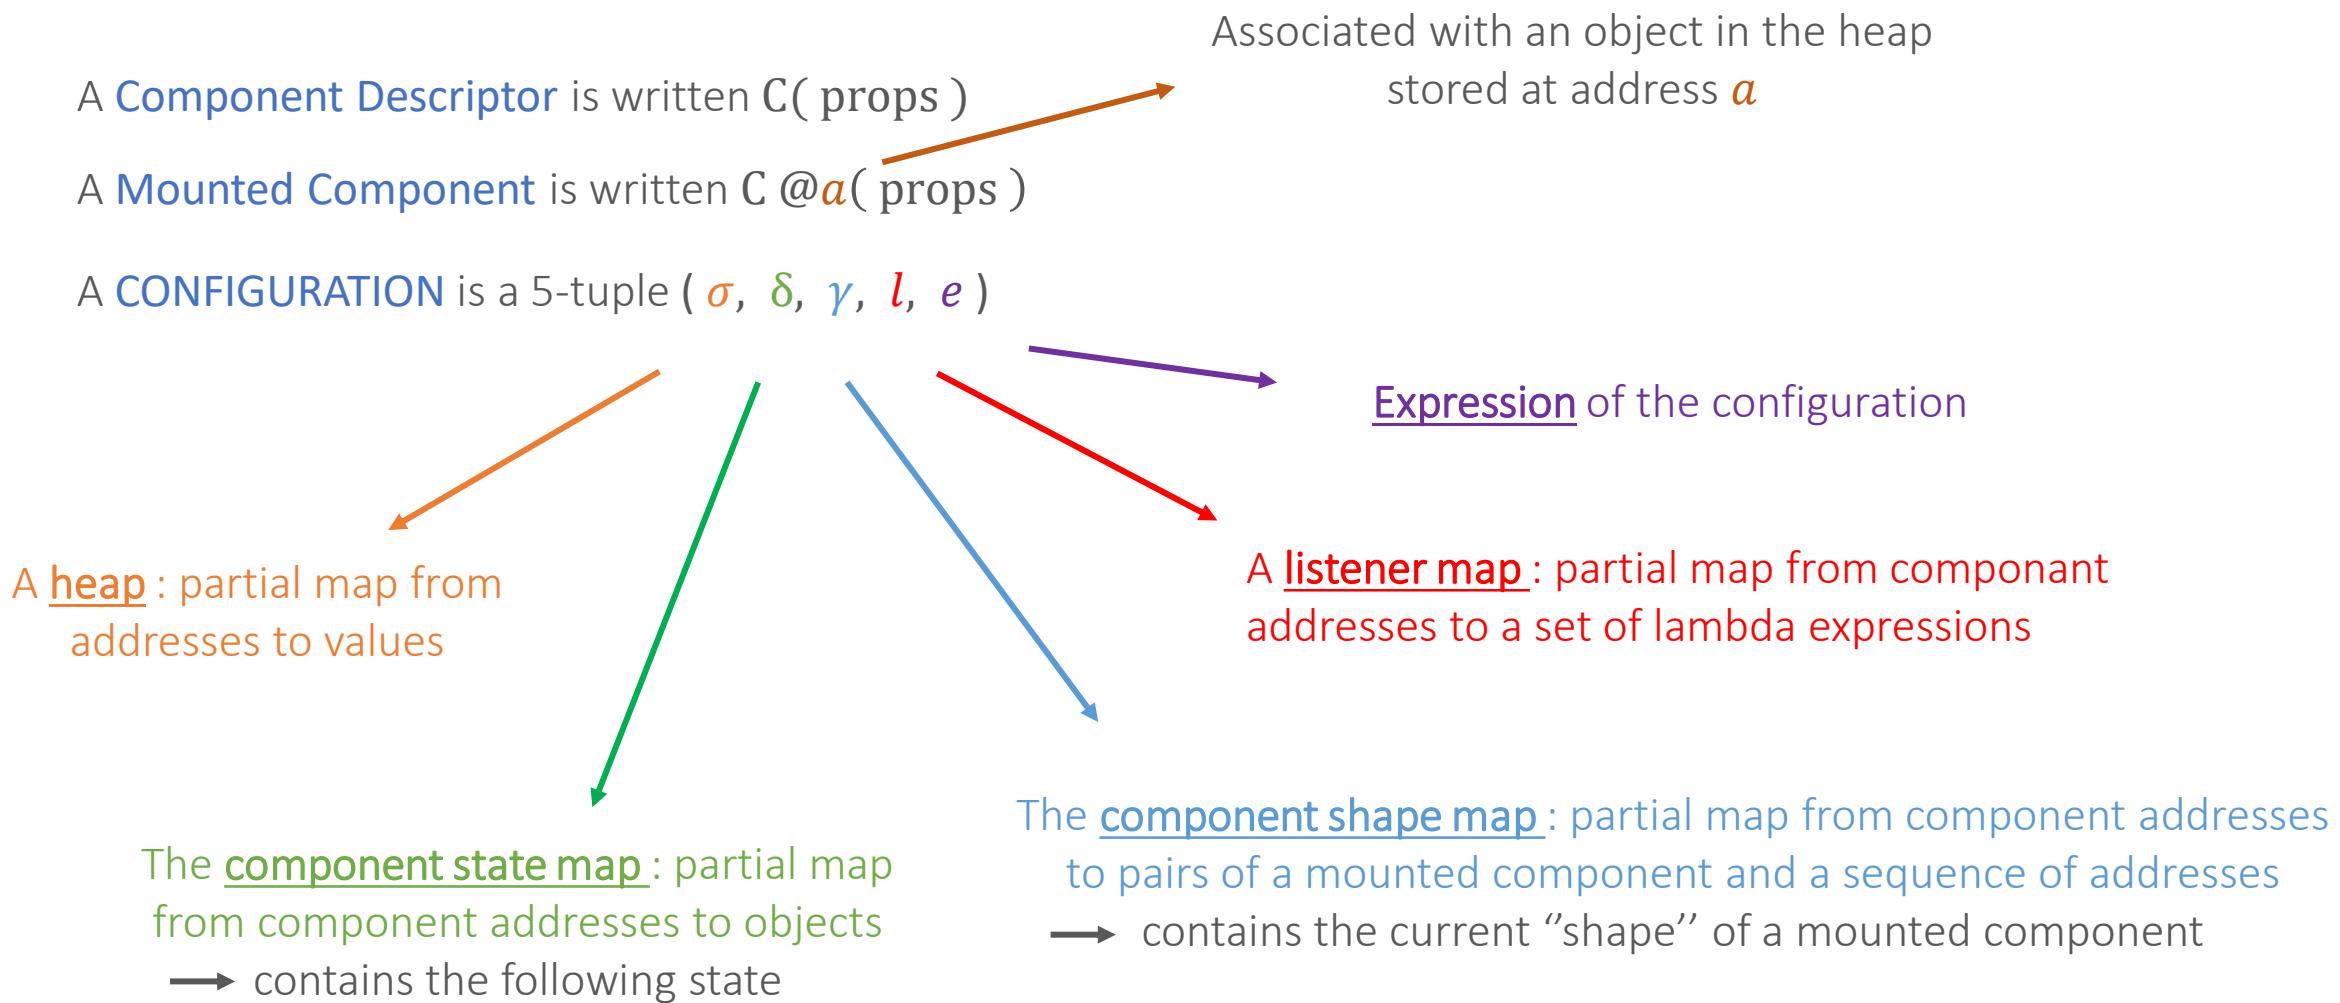

Set of .patl programs which are built with the concept of components top/low level

Set of Rendery programs composed of sequences of Rendery (Swift) instruction

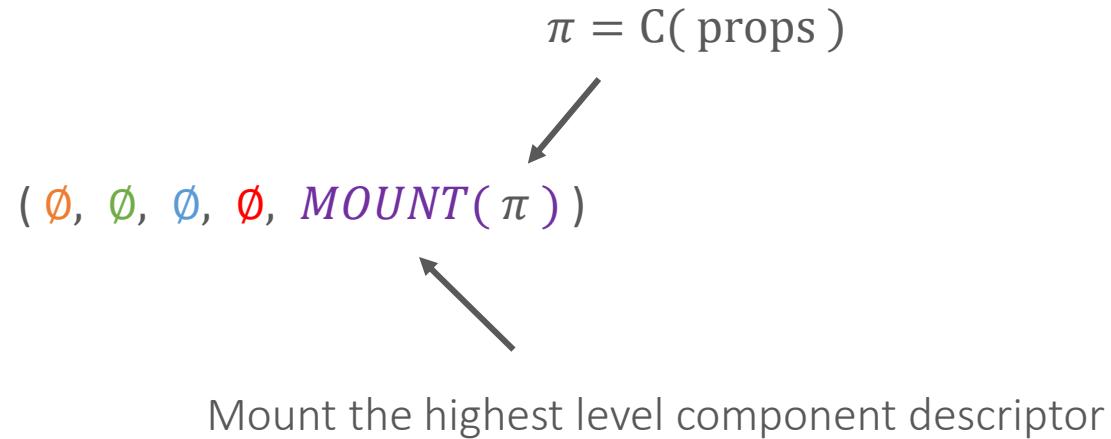

→ Then we send it to an interpreter

# Operational semantics

# Operational semantics

INITIAL STATE

# Operational semantics

## MOUNT (Initialization step)

We want to mount component  $a$  addressed with  $\pi$  and update the present state map  $l$

$$\begin{array}{ccccc} \swarrow & \searrow & \downarrow & \downarrow & \downarrow \\ \pi = C(\text{props}) & a \notin \text{dom}(\sigma) & \sigma' = \sigma[a \rightarrow \{\text{props}\}] & \delta' = \delta[a] & l' = l[a] \end{array}$$

---

$$(\sigma, \delta, \gamma, l, MOUNT(\pi)) \longrightarrow (\sigma', \delta', \gamma, l', MOUNTED(C @ a(\text{props}), MOUNTSEQ(RENDER(\pi))))$$

Update the **component shape map** to reflect the current “shape”  
of component  $a$  and its current subcomponents

Recursively mount its subcomponents

$$\gamma' = \gamma[a \rightarrow (C @ a(\text{props}), \bar{a})]$$

---

$$(\sigma, \delta, \gamma, l, MOUNTED(C @ a(\text{props}), \bar{a})) \longrightarrow (\sigma, \delta, \gamma', l, a)$$

# Operational semantics

UNMOUNT

Subcomponents of  $a$  are known from  $\gamma$

$$\gamma(a) = (\mathcal{C} @a(\text{props}), \bar{a})$$

First, unmount subcomponents of  $a$

---

$$(\sigma, \delta, \gamma, l, \text{UNMOUNT}(a)) \longrightarrow (\sigma, \delta, \gamma, l, \text{UNMOUNTSEQ}(\bar{a}); \text{UNMOUNTED}(a))$$

Once the subcomponents of  $a$  have been unmounted, remove all listener (event)

$$l' = l - a$$

---

$$(\sigma, \delta, \gamma, l, \text{UNMOUNTED}(a)) \longrightarrow (\sigma, \delta, \gamma, l', \text{NIL})$$

# Operational semantics

## OBJECT EQUALITY

Compare the values of primitive types by equality

They share the same keys

$\forall k \in \text{keys}(o_1) \ o_1(k) \text{ is primitive} \Rightarrow o_1(k) == o_2(k)$

$$\text{keys}(o_1) = \text{keys}(o_2)$$

References are compared using reference equality

$$o_1 \equiv o_2$$

# Operational semantics

## STATE MERGES

Take all keys and values from the left object

$$\forall k_i \in \text{keys}(o_1), o_1(k_i) = v_i$$

Take all keys and values from the right object that did not appear in the left one

$$\forall k'_i \in (\text{keys}(o_2) - \text{keys}(o_1)), o_2(k'_i) = v'_i$$

$$o_3 = \{k_1: v_1, \dots, k_n: v_n, k'_1: v'_1, \dots, k'_n: v'_n\}$$

---

$$\text{MERGE}(o_1, o_2) = o_3$$

Add all keys and value into a new object

# Operational semantics

RECONCILIATION (update a mounted component)

First case: a mounted component is replaced by another one

The new component we want to replace the component at the address and descriptor and mounted components are different

$$\pi = C_1(nextprops) \quad \gamma(a) = (C_2 @a(prevprops), \_) \quad C_1 \neq C_2$$

---

$$(\sigma, \delta, \gamma, l, RECONCILE(\pi, a)) \longrightarrow (\sigma, \delta, \gamma, l, UNMOUNT(a); MOUNT(\pi))$$

Mounted component is unmounted & we mount  $\pi$

# Operational semantics

Second case: update a mounted component with news props & state

The same component with the  
news props we want

Update the component at the address  $a$

Get the next state of the component

$$\pi = C(nextprops)$$

$$o = \sigma(a)$$

$$\gamma(a) = (C @a(props), \bar{a})$$

$$o' = o[props \rightarrow nextprops] [state \rightarrow nextstate]$$

$$nextstate = \delta(a)$$

$$\sigma' = \sigma[a \rightarrow o']$$

$$(\sigma, \delta, \gamma, l, RECONCILE(\pi, a))$$

$$\xrightarrow{\quad}$$

$$(\sigma', \delta, \gamma, l, RECONCILED(C @a(props), \bar{a}), RECONCILESEQ(RERENDER(a, \bar{a})))$$

Object  $o$  represents the component object

Update the props & state fields

Update  $\sigma$  at the address  $a$

$$\gamma' = \gamma[a \rightarrow (C @a(props), \bar{a})]$$

Re render  $a$  which gives us  $\bar{\pi}$  and apply  $RECONCILE$  on the subcomponents

Update the component shape map to reflect the current "shape" of component  $a$  and its current subcomponents

$$(\sigma, \delta, \gamma', l, a) \longrightarrow (\sigma, \delta, \gamma', l, a)$$

# Operational semantics

**RENDERS**

We want to render  $\pi$

Invoke the render method of the component

$$\pi = C(\text{props}) \quad (\sigma, \delta, \gamma, l, \text{render}()) \rightarrow (\sigma, \delta, \gamma, l, \bar{\pi})$$

---

$$(\sigma, \delta, \gamma, l, \text{RENDER}(\pi)) \longrightarrow (\sigma, \delta, \gamma, l, \bar{\pi})$$

**RERENDER (for a mounted component)**

Return the sequence of remaining components

Use the address  $a$  to retrieve the component from  $\gamma$

$$\gamma(a) = (C @ a (\text{props}), \_) \quad (\sigma, \delta, \gamma, l, \text{render}()) \rightarrow (\sigma, \delta, \gamma, l, \bar{\pi})$$

---

$$(\sigma, \delta, \gamma, l, \text{RERENDER}(a)) \longrightarrow (\sigma, \delta, \gamma, l, \bar{\pi})$$

# Operational semantics

## UPDATERSTATE

Use the address  $a$  to retrieve the component from state of the component

$$\gamma(a) = (\text{C} @ a (\text{props}), \bar{a})$$

$$nextstate = \delta(a)$$

$$\delta' = \delta[a \rightarrow \text{MERGE}(newstate, nextstate)]$$

---

$(\sigma, \delta, \gamma, l, \text{UPDATERSTATE}(a, newstate)) \rightarrow (\sigma, \delta', \gamma, l, \text{RECONCILED}(a, \text{RECONCILESEQ}(\text{RENDER}(a), \bar{a})))$

The  $newstate$  object is passed to the component

Changing the state of a component could change what is returned by its render method

# Call OpenGL from Swift (Linux)

An OpenGL function loader in pure Swift

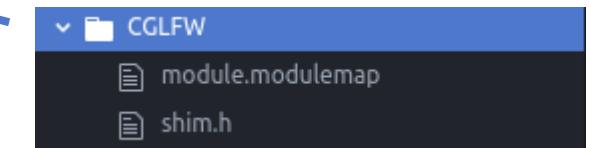

It can load any OpenGL function up to OpenGL 4.5

```
import PackageDescription

let package = Package(
    name: "test_OpenGL_swift_linux_SPM",
    products: [
        .executable(name: "UsageExample", targets: ["UsageExample"]),
    ],
    dependencies: [
        // Dependencies declare other packages that this package depends on.
        // .package(url: /* package url */, from: "1.0.0"),
        .package(url: "https://github.com/apple/swift-numerics", from: "0.0.5"),
        .package(name: "GL", url: "https://github.com/kelvin13/swift-opengl.git", .branch("master"))
    ],
    targets: [
        // Targets are the basic building blocks of a package. A target can define a module or a test suite.
        // Targets can depend on other targets in this package, and on products in packages this package depends on.
        .target(name: "UsageExample", dependencies: ["test_OpenGL_swift_linux_SPM"]),
        .target(name: "test_OpenGL_swift_linux_SPM", dependencies: ["GL", "CGlad", "CGLFW", "CFreeType"]),
        .target(name: "CGlad", dependencies: []),

        .systemLibrary(name: "CFreeType", pkgConfig: "freetype2"),
        .systemLibrary(name: "CGLFW", pkgConfig: "glfw3"),

        .testTarget(
            name: "test_OpenGL_swift_linux_SPMTests",
            dependencies: ["test_OpenGL_swift_linux_SPM"]),
    ]
)
```

Import the OpenGL function loader & the other important libraries

```
import GL
import CGLFW
import CFreeType
import Foundation
```

```
// Initialize GLFW
if(glfwInit() == 0) {
    print("Failed to initialize GLFW! I'm out!")
    exit(-1)
}
```

```
guard let window = glfwCreateWindow(600, 600, "OpenGL test - Swift", nil, nil)
else {
    print("Failed to open a window! I'm out!")
    glfwTerminate()
    exit(-1)
}

// Set the window context current
glfwMakeContextCurrent(window)
```

Open a window & attach an OpenGL context to the window surface

Red background

Draw a yellow square

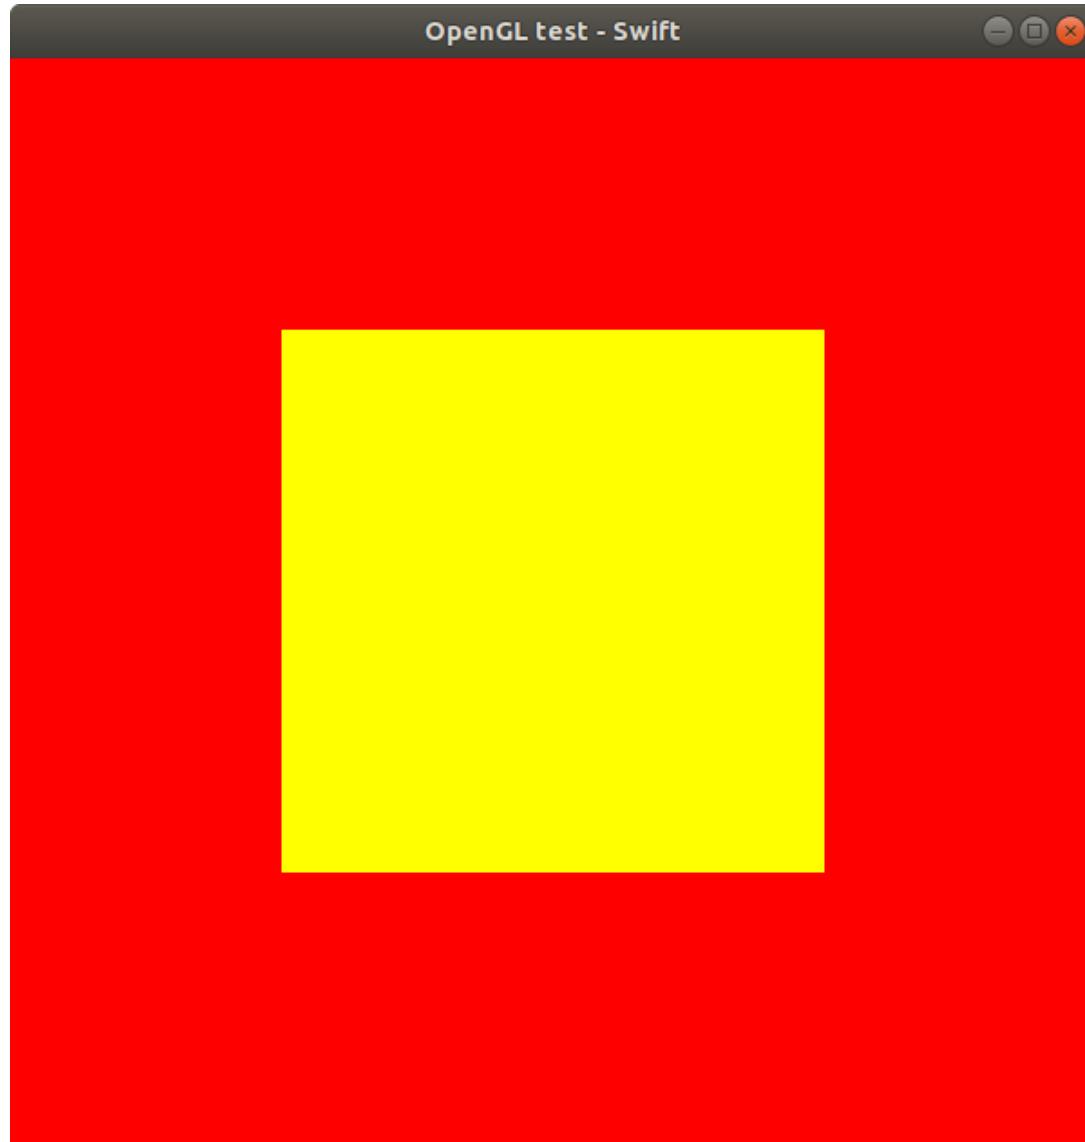

```
// Use red to clear the screen
glClearColor(1, 0, 0, 1)
while (glfwWindowShouldClose(window) == 0) {
    // Clear the screen (window background)
    glClear(UInt32(GL_COLOR_BUFFER_BIT))

    // Draw a square using the (deprecated) fixed pipeline functionality
    glColor3f(1.0, 1.0, 0.0)
    glBegin(GL_QUADS)
    glVertex2f(-0.5, -0.5)
    glVertex2f(0.5, -0.5)
    glVertex2f(0.5, 0.5)
    glVertex2f(-0.5, 0.5)
    glEnd()
    // Swap front and back buffers for the current window
    glfwSwapBuffers(window)
    // Poll for events
    glfwPollEvents()
}

// Destroy the window and its context
glfwDestroyWindow(window)

// Terminate GLFW
glfwTerminate()
```

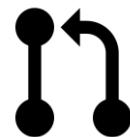

Swift build  
Swift run

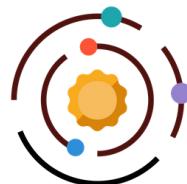

# Rendery on Linux

Rendery is now operational on Linux

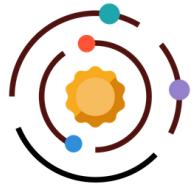

I sent a pull request

Then, the idea was to work on the example of the solar system

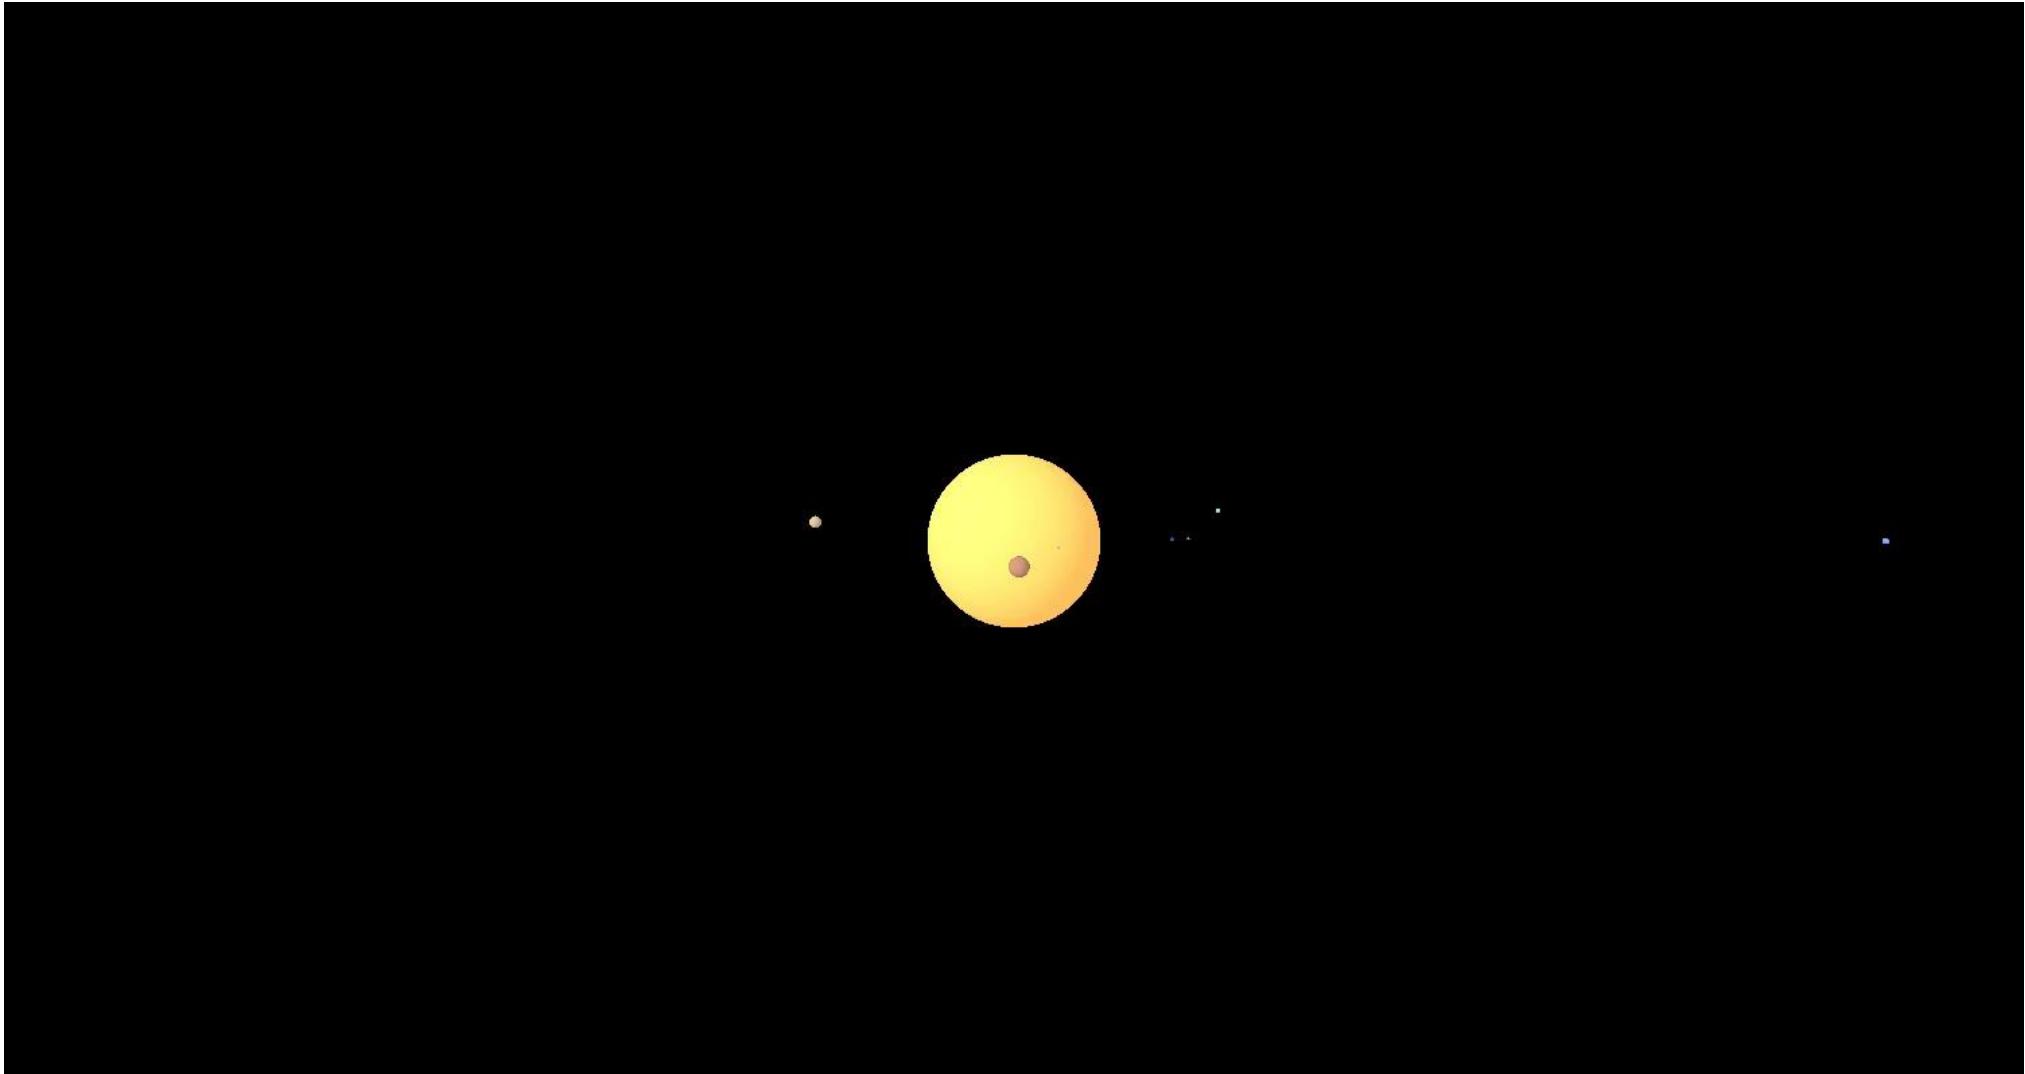

# How it works

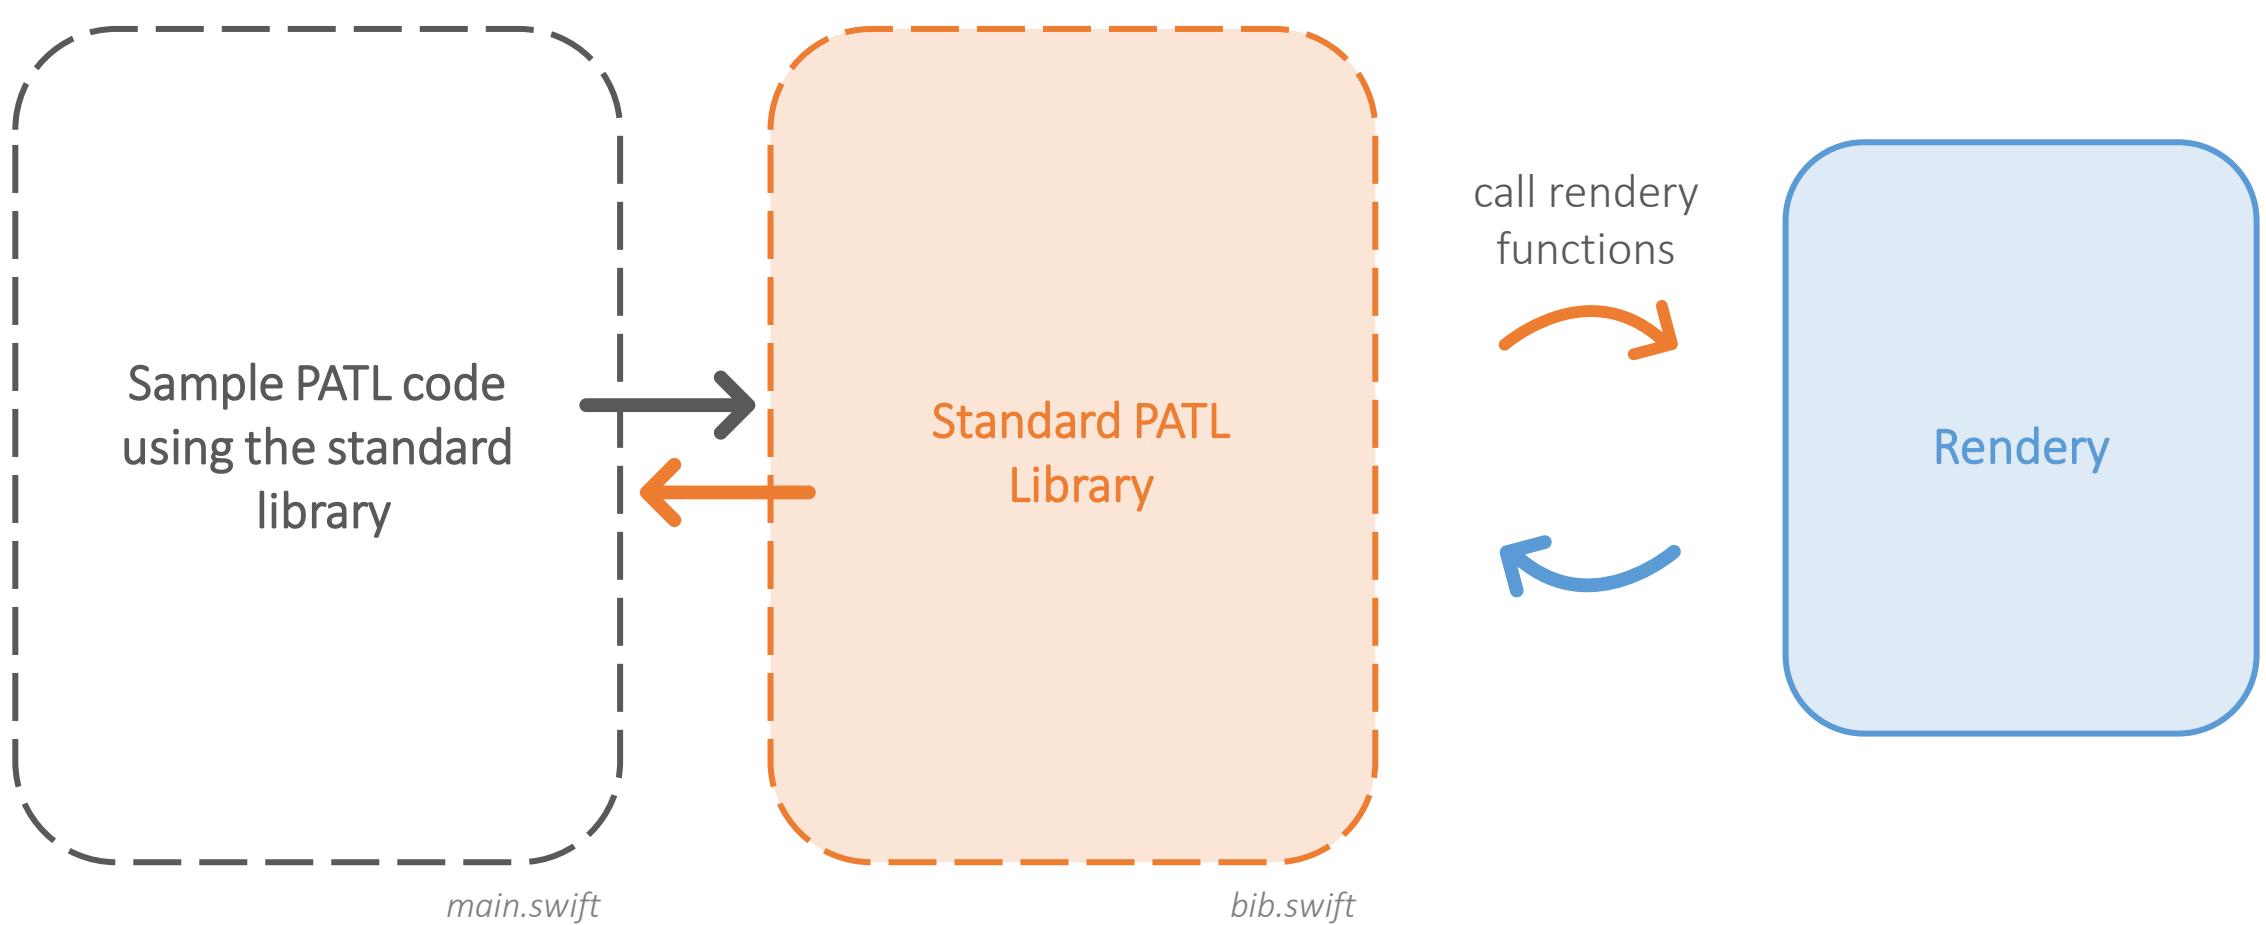

Create a context and attach a window to it

- └ Create a scene where we will place our 3D objects
  - └ Create child nodes that will define our objects
    - └ Define a camera that will be the point of view of the users
    - └ ...
    - └ Create spheres representing our planets
      - └ Update the position of the planets

# Solar system with Rendery

# Principal idea of PATL

# Example with the solar system

```
class SystemSolar: ComponentTopLevel {  
  
    var state: [String: [String: Any]] = [:]  
    let solarRadius: Double = 50.0  
  
    override init() {  
        super.init()  
        // Define the background color as "#000000"  
        self.setBackgroundColor(colHexa: "#000000")  
        // Define the global state of the application: this is a dictionary of dictionaries.  
        // Each object in the scene has some properties.  
        // Here, each planet has a name, a radius, coordinates (polar: which are represented by the distance from the sun and the polar angle),  
        // a revolution and finally an image representing its texture.  
        self.state = ["root": ["name": "Solar",  
                            "radius": solarRadius,  
                            "coord": Coord(polar: (0.0, Angles(deg: 0.0), Angles(deg: 0.0))),  
                            "tex": "/img/solar_tex.jpg"],  
                    "obj0": ["name": "Mercury",  
                            "radius": self.sizePlanet(s: solarRadius, p: 11440),  
                            "coord": Coord(polar: (self.distPlanet(s: solarRadius, d: 35.791), Angles(deg: 0.0), Angles(deg: 0.0))),  
                            "revo": 88.0,  
                            "tex": "/img/mercury_tex.jpeg"],  
                    ...  
                    self.render()  
    }  
}
```

```
// Build the Scene related to ComponentTopLevel  
open class ComponentTopLevel: Scene {  
    public override init() {  
        // Set the background color of the scene  
        public func setBackgroundColor(colHexa: Color) -> Color {  
            backgroundColor = colHexa  
            return backgroundColor!  
        }  
        cameraNode.camera?.farDistance = 5000.0  
        cameraNode.translation = Vector3(x: 650.0, y: 100, z: 100)  
        cameraNode.constraints.append(LookAtConstraint(target: root))  
    }  
}
```

    // Run the rendering loop.
    ApplicationContext.shared.targetFrameRate = 60
    ApplicationContext.shared.render()
}
```

bib.swift

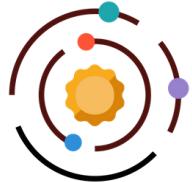

# Solar system with PATL

# Work done

Successfully run Rendery on Linux

Implement the solar system example with Rendery

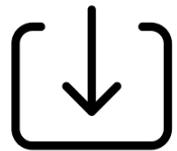

# Advancement

Debugging and coding new Rendery features (PATL library) such as:

Abstract types

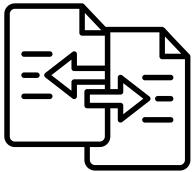

Import and use of shader programs

Events

# Shader part

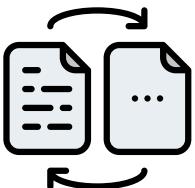

Write shaders in GLSL and pass them to Rendery

We can use shader libraries for examples

Ex: (a Shader Editor: [shdr.bkcore.com](http://shdr.bkcore.com) , ... )

Then a step could be to create our custom shaders with a Swift syntax and convert them to GLSL shaders

→ With a parser, etc.

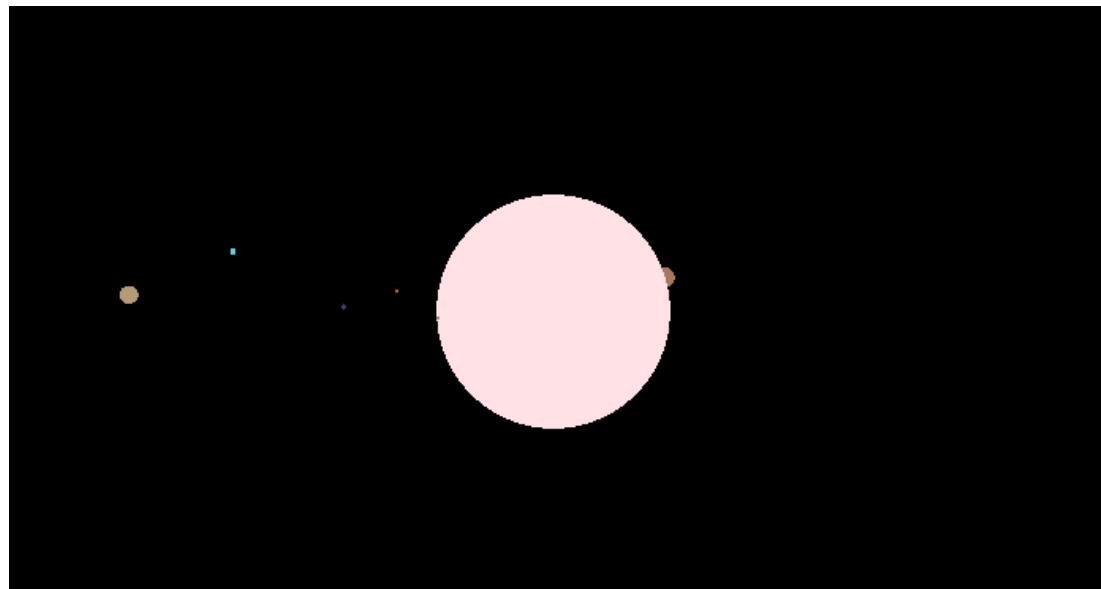

# Shader part

```
public let fragmentSource = """
#version 330 core
out vec4 FragColor;
in vec4 vertexColor;
void main() {
    FragColor = vertexColor;
}
"""
```

*pinkProgram.swift*

```
public let vertexSource = """
#version 330 core
layout (location = 0) in vec3 i_position;
uniform mat4 u_modelViewProjMatrix;
out vec4 vertexColor;
void main() {
    gl_Position = u_modelViewProjMatrix * vec4(i_position, 1.0);
    vertexColor = vec4(1.0, 0.75, 0.79, 1.0);
}
"""
```

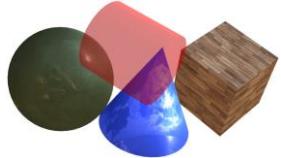

*pinkProgram.swift*

# Work in progress

Implement the PATL to Rendery translation system  
(PATL standard library)

Work on the shaders part and create examples of applications

Develop a tutorial to explain how to use PATL
